The Young Publisher's Progress. Assuming that he is determined to be no mere employee in a department, but has set his mind on a managerial post at least, we shall suppose him to have had, first of all, a reasonable knowledge of English literature [see LITERATURE], and if he gives evidence of any literary taste and judgment, he will not find it difficult, after he has spent some time in the Costing Department, where he will have become familiar with the cost of producing a book and the various qualities of material used, in getting into the Production Department, the scope of which varies greatly in accordance with the importance of the firm. Here the duties consist of keeping account of all accepted MSS., arranging with the printers for specimen pages, and estimating the size of books, deciding upon the style of title-pages, bindings, general get-up, and proof reading. It is, in a word, the department in which all the practical detail of production occurs, from which the MS. of a book is handed to the printer, and from which the first completed book is handed over to the manager. In the smaller firms this department is concerned also with drawing up the spring and autumn catalogues, but in the large houses that important part of a publisher's business usually falls to the lot of the Publicity Department.

It will be gathered from our qualifying references that it is very difficult to speak of the publishing trade in general terms. There are many publishers earning a good livelihood who employ no more than half-a-dozen assistants, and unite in themselves all the different departments we have mentioned. In fact, it is no bad plan for a young man to attach himself to one of these smaller publishers, as the variety of work which will fall to his share every day will result in his acquiring a very good knowledge of the trade more speedily than it could be acquired in one of the larger firms.

The Work of the "Literary Adviser." The office routine of a large publishing house is, of course, very much the same as that of any other business, but the young man who has shown sufficient literary aptitude to be placed in the Production Department is fairly certain to be employed sooner or later in the reading of MSS., and in consultation with the manager preliminary to the acceptance of a work. The "literary adviser" used to be a somewhat mysterious person who read all the MSS. received, and supplied reports as to their literary qualities and the likelihood of their success. He was sometimes himself a distinguished novelist, who thus eked out some extra income by giving what was very frequently the most misleading advice. This old-fashioned type of adviser is disappearing. The successful publisher of to-day depends hardly at all upon the unsolicited MSS. he receives. They are read and reported on as of old, but his reader, if he himself does not do the work, is more likely to be some alert person with the real journalist's knowledge of what is calculated to interest the public, and it will be found that he or the publisher himself will be the first to think of most of the books they will publish. As a matter of fact, the ideal publisher, or literary adviser, is essentially an ideal editor. The editor of a successful magazine has a certain public, or perhaps several publics, in mind when he sits down to plan out his next number. In order to secure an attractive programme, he will ask a certain number of distinguished writers each to contribute a story of a certain kind and a given length. He will arrange so many articles to suit this section or that section of his readers, and he will ask certain writers to prepare them. He will then decide how many pages each is to occupy, including illustrations, and will carefully choose the artist who can best do the different kinds of pictures he requires. Hence, although he may receive 200 MSS. per week, he will seldom retain more than two, and nothing but the fear of missing a good article by an unknown writer induces him to wade through the MSS. Now, if for stories and articles we substitute novels and books of biography, travel, and general literature, the publisher is engaged in precisely the same work as the editor. This indicates that one may come to publishing through editing; but, of course, for such a one the SELF-EDUCATOR is hardly likely to be a guide.

"A Genius for Publishing." It is unnecessary here to dwell upon such technical details as the arrangement of a book, the various sizes of paper, types, illustrations, printing, and book-binding. All these matters are dealt with in other parts of the present course, and with them the beginner in book production must necessarily and speedily familiarise himself. In the little space that remains to us we must confine ourselves to the general aspects of publishing, and need we say that after every possible tittle of information touching the practical side of the business has been acquired, if the intending publisher is not gifted with the peculiar acumen that makes the successful editor and the prosperous publisher, he may have studied and prepared for the work in vain? There is some touch of genius in knowing just what is likely to meet the tastes of the many different sections of the public, and without this all the technical knowledge in the world will avail nothing. Every day of our life we see books being published which we know cannot possibly succeed. Sometimes this is the bad judgment of the publisher; again, it may be the foolishness of the vain writer, who has paid some publisher to issue the work, but publishers who do this never rank high in the profession.

Risky Publishing and Safe. Not very well can we lay down any rule as to the amount of capital that is required to engage in publishing. Everything will depend upon one's personal requirements and how soon a return for one's money will be expected. This, however, can be said, that cheap publishing requires by far the largest amount of capital. That is to say, to deal largely in attractive editions of non-copyright books at cheap prices involves a much greater risk than the publishing of original works in general literature, in editions of, say, one thousand copies, at good prices, from six shillings upwards; and if the possibilities of the more expensive publishing are not quite so great, the money invested is far safer and likely to produce a substantial return. Novels, and fiction of all kinds, involve a much greater element of risk than works of biography and travel; but it is an axiom of the trade that educational and technical books are of all the most desirable to publish, as they supply a demand that can be easily gauged, and if at all well done, cannot easily fail to be profitable.

MAN AGAINST BACTERIA

The Facts of Immunity. The Fates of Nations Decided by Bacteria. Empires Founded on Immunity to Disease. Immunity from Moral Disease

Continued from page 6544

By Dr. GERALD LEIGHTON

BEFORE proceeding to the next portion of our subject, it will be well to summarise briefly the important bacteriological facts bearing upon the causation of disease and production of immunity.

Bacteria produce their effects either by their own multiplication or by the manufacture of poisonous toxin. Some diseases, such as anthrax, are due mainly to the former process. These are termed septicæmias. Others are chiefly dangerous from the toxic action of the microbe—for example, tetanus or lockjaw. Hence, substances which prevent or cure microbic disease are either anti-bacterial or anti-toxic, according to the nature of the particular disease. Immunity is of two different types—natural or acquired. Natural immunity belongs to the individual in virtue of his being the person he is, a person of a given species, race, family, temperament, and idiosyncrasy. It is a product of evolution, and hence is found to show itself in various directions in different species and races. Because it is inborn, it can be, and is, transmitted by heredity; it cannot be transferred from one individual to another. Acquired immunity, on the other hand, comes to a person in one of two ways—either as the result of recovering from disease, or as the result of artificial inoculation. Because it is acquired, it cannot be, and is not, transmitted by heredity. But it can, by suitable methods, be transferred from one individual to another.

Disease Cured by Horse Serum.

The most perfect method of thus transmitting an acquired immunity is to be seen in the serum treatment of disease. This depends upon the fact that when a susceptible animal is artificially made to acquire immunity, the serum of that animal contains substances which are either anti-bacterial or anti-toxic. This serum can be readily withdrawn from the animal in question, can be preserved for a considerable length of time, while it retains its properties, and can thus be used at any moment when required as a curative agent. Such a serum, to be depended upon, must be taken from a highly immunised animal; it must have, in other words, a high anti-toxic value. By this is meant that a given quantity of that serum must be of such potency as will enable it to antagonise a large quantity of toxin in a patient. It is not sufficient that it merely be anti-toxic: it must be highly anti-toxic. The reason is obvious. It is impossible for the physician to estimate in a case, for example, of diphtheria, how much toxin is present in the body of his patient as the result of the action of the microbe of that disease. There may be little; there may be much. There may be little to-day, but sufficient to-morrow to kill the patient. In order that the anti-toxic serum may be reliable, it follows that the dose of that serum must contain sufficient anti-toxin to antagonise the largest quantity of toxin which is likely to be present in any case of diphtheria.

A serum of this high immunising power is obtained from the horse by rendering that animal immune, not merely from ordinary doses of diphtheria anti-toxin, but from doses which, under ordinary circumstances—that is, were the animal not immunised—would be much more than sufficient to cause a fatal result. The bacteriologist, whose business it is to prepare a serum has definite tests by which he is able to "standardise" his serum, which is therefore always of a known potency. Not only so, but he is able to increase or decrease the virulence of disease-producing microbes by various methods of cultivation, and so able to produce immunity from a more virulent microbe than the one which usually causes the disease itself.

The advantage of using a serum to confer acquired immunity is that its anti-toxic properties are available for instant service. It is a curative agent. The disadvantage of conferring an acquired immunity by a serum is that such an immunity lasts but a short time. The serum is a foreign substance, and, as such, tends to be eliminated from the system before very long. Meantime, however, it has done its work of healing. The advantage of acquiring immunity by recovery from disease is that such an acquired immunity lasts for a long period—perhaps years, perhaps a lifetime. The disadvantage of this process is that the patient has to make his own anti-toxic substance while suffering from the disease. It is therefore only of value as a preventive agent against future infection.

The Place of Bacteria in Evolution.

It is surely a wonderful thought that these microscopic bacteria contain within them the fate of nations; but such is indeed the case. It would be difficult to think of any one class of agency which has been such a potent factor in the past history of the evolution of mankind, and which is still in active operation to-day. We have seen in another part of this work [see BIOLOGY] that organic evolution means *adaptive change*, and that the most powerful factor in its production is natural selection of the fittest to survive. Any agency, therefore, which operates by eliminating huge numbers of individuals must be a most potent cause of racial evolution. In fact, the evolution of any nation is that of its immunities from the various deleterious influences to which it is subjected. Restricting ourselves for the moment to what we term the physical sphere, and in that sphere to the domain of disease, it is thus quite obvious that the evolution of a nation or a race will depend upon the evolution of immunity from various diseases, or else upon the evolution of the power of acquiring immunity. Take our own race as a case in point.

For very many generations the people in these isles have been subject to the infection of tuberculosis, or consumption. Now, the microbe of this disease, the tubercle bacillus, flourishes best in the environment of what we term "slums." In these "slums" are gathered together in dense crowds great numbers of our population. Nothing but a strong power of resistance—that is, immunity—could possibly prevent the utter extermination of people under such conditions, and, as a matter of fact, as we know, many do so perish. But why not all, or a great many more than do? Obviously, there has been evolved in our race an inborn power of resistance, an inborn immunity. How has it been

evolved? In the usual way, by natural selection of the fittest to survive. Who were the fittest in this particular case? Those who possessed by nature already some power of resistance. The others, the less resistant, have been in process of elimination for generations. Thus is gradually being evolved in our race an inborn immunity from this particular disease. If we wish to see what happens in the absence of such evolution we have only to notice the effect of this disease upon a race previously unexposed to it. Its ravages are terrible.

Measles as a National Disaster. Take another case—that of measles. Here we have a disease to which every Englishman is still susceptible, but against which, all the same, there has been great racial evolution in a different direction. Measles in this country, apart from any complications, is considered a trifling complaint. We know from experience that nearly every case will end in recovery. But when measles is introduced amongst a race to which it was previously unknown, the Polynesians, for example, its effects are so severe that a large proportion will perish. Why? Because the Englishman has undergone a process of evolution against measles of which the Polynesian has had no opportunity. But note the Englishman still gets measles. He has not evolved any immunity from infection. He is as susceptible as ever, apparently. What he has evolved is the capacity to recover—in other words, the power of acquiring immunity. How has this been accomplished?

Obviously, again, it is a question of natural selection. Once more the unfit have gone to the wall. When measles first attacked us, those individuals only who had the power of recovery and of acquiring immunity survived. This was an inborn power capable of transmission by heredity to their descendants. In this way each succeeding generation became more and more capable of acquiring immunity from measles. And this would go on as long as measles was a selective agent.

Thus, in some infectious diseases which affect large numbers of people there is evolved by natural selection an inborn immunity from infection. In other diseases there is evolved the power of acquiring immunity from the effects of the disease. These two processes are perfectly distinct, but both proceed along similar lines of evolution and are the cause of the racial differences of susceptibility to disease which we see in the world to-day.

"Modern examples of ancient epidemics," as Dr. Archdall Reid says, "may be seen in isolated regions. In Pacific islands, for example, air-borne disease spreads like a flame. The whole community is stricken down. The sick are left untended and perish in multitudes. The fields, the entire business of the community, are neglected, and famine frequently follows. Under such conditions measles or whooping-cough—diseases which we in England are accustomed to regard as scarcely more than nuisances—may rise to the level of a great national disaster. Thus, in 1749, thirty thousand natives perished of measles on the banks of the Amazon. In 1829 half the population died in Astoria. In 1846 measles committed frightful ravages in the Hudson Bay Territory. More recently a quarter of the total inhabitants was swept away in the Fiji group."

Evolution against Consumption. "The progress of consumption was different. It was never truly epidemic. Owing to its low infectivity, to its lingering nature, to the fact that no immunity from it could be acquired, it did not spread suddenly when first introduced, but when once established its virulence did not abate within measurable time. In other words, it was endemic from the beginning. It made its home in the hovels of the early settlers on the land. In such situations—as in Polynesian villages—modern Englishmen do not take the disease. But their remote ancestors were more susceptible; they could be infected by a smaller dose of bacilli. Gradually, as civilisation advanced, the conditions became more stringent; men gathered into larger and denser communities, into hamlets and villages, in which they built houses ill-lighted and worse ventilated. With the rise of towns, and ultimately of great cities, the stringency of selection continually increased, and with it, step by step, the resisting power of the race. To-day Englishmen dwell under conditions as impossible to their remote ancestors as to the modern Red Indians. In fact, no race, especially in cold and temperate climates, is now able to achieve civilisation, to dwell in dense communities, unless it has previously undergone evolution against tuberculosis.

"So during the long sweep of the ages the microbic diseases strengthened their hold on the inhabitants of the eastern hemisphere, who, in turn, slowly evolved powers of resistance. In like manner antelopes grow swift and wild sheep active when persecuted by beasts of prey. Then, when the germs of disease were rife in every home and thick on the garments of every man, there occurred the greatest event in human history, the vastest tragedy. Columbus, sailing across an untracked ocean, discovered the western hemisphere. The long separation between the inhabitants of the East and the West ended. The diseases of the Old World burst with cataclysmal results on the New."

Bacteria as Empire Builders. Then, of course, what had already happened in the Old World had all to be undergone again in the New. Once more plague and pestilence held the field, with great epidemics, followed by famine. In the same way, when smallpox was taken to the West Indies in 1507, whole tribes were exterminated, and shortly afterwards the same fell disease depopulated San Domingo. Three-and-a-half million human beings perished from it in Mexico. Catlin, in 1841, wrote of the United States, that "thirty millions of white men are now scuffling for the goods and luxuries of life over the bones of twelve millions of red men, six millions of whom have fallen victims to smallpox." And so the white man spreads over the so-called uncivilised portion of the globe and inhabits the choicest places previously occupied by others, simply because it has been his lot to have evolved in the course of ages an immunity from some infections and a power of acquiring immunity from others. So the Spanish conquest of the West Indies was followed by the rapid disappearance of the natives, who acquired the diseases imported by every vessel. The striking lesson that bacteriology teaches the empire-builder is that any conquest, in order to be permanent, must be accompanied by extermination, for otherwise, in the course of time, the native will either absorb or expel the conquerors. Dr. Reid says "The Saxon conquest of England was permanent; of the Norman conquest there remains scarcely a trace. The Huns and the Franks founded permanent empires in Europe; the Roman Empire and that of the Saracens in Spain soon tumbled into ruins. It is highly improbable, therefore, that the British will retain their hold on their Old World dependencies. A handful of aliens cannot for ever keep in subjugation large and increasing races that yearly become more intelligent and insistent in their demands for self-government. But no probable conjunction of

circumstances can be thought of that will uproot the Anglo-Saxons from their wide possession in the New World. The wars of extermination are ceasing with the spread of civilisation. We have ransacked the world, and now know every important disease. Diseases cannot come to us as they came to our forefathers and to the Red Indians, like visitations from on high. All the diseases that are capable of travelling have nearly reached their limits; the rest we are able to check. Even in the unlikely event of a new disease arising it would affect other races equally. Canada and Australasia, like the United States, may separate from the parent stem, but the race will persist. If ever a New Zealander broods over the ruin of London he will be a New Zealander of British descent."

New Empires no longer Possible. Thus in plain fact is the natural history of man nothing more than the story of his evolution against bacterial diseases. It is a humbling thought but a true one that the conscious efforts of man have had but little influence upon his destiny in comparison with his unconscious struggle to evolve against the most minute of living creatures. The time for founding new empires has gone for ever. Only a few malarious districts remain. Other nations had their opportunity and threw it away by choosing the tropics for their empire instead of the temperate climes, as was the case with Spain and Portugal. "France lost her opportunity on the Heights of Abraham. Germany is more than a century too late in the start. Russia can conquer only hardy aliens, who will multiply under her rule and ultimately assert their supremacy." To Great Britain alone was it given early enough to evolve immunity from the most devastating of bacterial diseases, and the wisdom or good fortune to colonise those portions of the world where this advantage placed the land at her mercy.

In this brief survey of modern bacteriology we have seen the dawn of a revolution in the methods of medical treatment of disease, a revolution whose future results it is impossible to foresee. In the future of bacteriology lies the hope of the healing art. We have seen how bacteria have moulded the history of the world and particularly of our own race. It only remains to show that these same great principles are in operation in other spheres than those of bacteriology, and that the laws of immunity have a far wider application than has hitherto been supposed. The greatest discovery of all is made plain by the discovery of the laws of immunity in bacteriology—namely, the fact that these laws are operative also in the mental, moral, and religious life of man, as well as in his physical body.

THE HIGHEST AIM OF MAN, PHYSICAL AND MORAL

A great number of readers have now followed the present writer in the sections of this work dealing with the sciences of biology and bacteriology. In the former of these courses we studied the problem of organic evolution, and endeavoured to gain some clear idea as to how that evolution had come about. We watched the relentless principle of natural selection at work, selecting the fit in the struggle for existence and rejecting the unfit, the suppression of the individual for the good of the race. That is Nature's method of progress. Then in the course of bacteriology we have studied a special aspect of organic evolution, evolution against microbic disease, and realised something of what has taken place in past ages which makes it possible for modern civilisation to exist as we see it in our teeming cities. We have learnt that it is possible for a race to become immune from a disease, and for an individual to possess the power of acquiring immunity. More, we clearly see that, unless evolution produces individuals who are either immune, or can acquire immunity from disease, the nation composed of those individuals *must inevitably perish*.

Evolution Against Moral Disease. In what follows here the writer wishes to apply these same principles and laws to other phases of man's life, to show what, in his opinion, must constitute the scientific base of evolution in other spheres than those of disease—spheres to which, as far as he is aware, these laws have not been definitely applied. The view to be here stated is given with all humility; it will not appeal to all—no view can do that, because a hundred minds see the *same truth* from a hundred different aspects—but it is hoped that, as it has helped a few already, it may be of assistance to many more in showing that there is solid scientific ground for expecting certain definite results to follow equally definite lines of procedure in other parts of man's nature.

It will be taken for granted in what follows that the reader has made himself familiar with what is meant by "Immunity," and that he has clearly understood the two types of immunity described in BACTERIOLOGY under the names "Natural or Inborn Immunity" and "Acquired Immunity." It must also be clearly understood that we are not here attempting to construct an elaborate analogy. An analogy is a likeness between things in some respects when the things are otherwise entirely different. The attempt here is to apply the same *identical laws* to additional aspects of man's nature.

Wider Application of Laws of Immunity. If the laws of immunity mean anything, they convey the greatest truth in the world—namely, that by undergoing certain processes a man can become immune from certain agencies. This is the highest aim of man. Physically, mentally, morally, he who is immune from all that can work him evil is the perfect man. There can be no higher ideal for man than to become immune from all that will interfere with the perfect development of his physical, intellectual, and moral nature.

Therefore, we say advisedly that the laws which govern the production of immunity convey the greatest truth in the world. What is here advanced is the scientific application of those same laws of immunity in disease to other parts of man's nature. Disease is merely one phase of human life, and is not entirely physical. It has its mental and moral aspects. We therefore assume that these aspects are involved in the working out of immunity. It is contended that the mental and moral processes, as well as those of disease, can be explained, and their nature demonstrated, by the application of the well-known laws of immunity to that part of man's nature of which they are the outward expression. One cannot separate these from the rest of a man. They are just as much a part of him as is his bodily health. Just as the latter is first developed, and subsequently modified by various natural agencies, so we must believe that these mental and moral processes are similarly brought forth and modified. In a word, a man has been what he was, is what he now is, can be what he hopes to be, in virtue only of one great set of principles which we know as the laws of immunity.

We may now examine the facts of immunity in the non-physical world, just as we did in the course on BACTERIOLOGY in relation to disease. In the realm of moral disease the definition of the term would be as follows: Immunity is that condition of an individual in virtue of which he is able, either partially or absolutely, to resist temptation.

Immunity from Temptation. A close examination of the lives of men and women around us will soon make clear the fact that all have some power of resistance to the variety of moral infections—that is, temptations—by which they are surrounded, and to which they are continually exposed. If this were not so, all would be hopelessly immoral. The righteous and sober life would be impossible. Now, this capacity for resistance, which all possess more or less, is inborn, and, like that against disease, it varies immensely in different individuals. It also varies with the nature of the infection in the same individuals. The temptations of one man are not necessarily those of another, any more than are the weak points in his physical armour. Everyone knows that there are people who can, by virtue of this power of natural resistance, pass unscathed through certain moral infections which in others would inevitably produce moral death. Thus some are naturally sober, innately resistant to the special infection of alcohol. It is no credit to them, but it is something for which they should be profoundly thankful. Others are naturally honest; the temptation to steal simply does not touch them. On the other hand, there are individuals who are especially susceptible to one or other of what we term vices, in whom, that is to say, this natural power of resistance is lacking.

The next point to note is that this inborn immunity of the individual cannot be transferred from one to another. It is useless as a help to his fellow-man. It is only the man of like passions and susceptibilities as ourselves who, having become immune, can transfer his immunity to others. The person who has been vaccinated can provide vaccine lymph which can be used as a protection to others: but if he be insusceptible to vaccination by nature, he is useless for this purpose. So it is that some are born saints, so to speak, while others are born susceptible to moral infection.

In addition to this universal resistance, which all possess in varying degrees, we observe that after passing through some special temptations the individual has acquired an immunity from that special condition, an immunity which did not exist before passing through the experience in question. If the law operates here as it does in the case of disease, we should expect to find that this special immunity lasts in some cases for years, in others for a lifetime. So it is.

The Fallacy of "Sowing Wild Oats." The thought then occurs that since experience of temptations and sin (infection and disease) successfully overcome (recovery) may confer immunity, why not try and confer this immunity artificially by exposing individuals to the contagion? There are those who believe in the efficacy of this process, and who think it a good thing that "wild oats should be sown" in the hope of reaping immunity. But it must be remembered that those who are thus exposed to moral infection run the risk of moral death for themselves, and, for the time being, are centres of infection for others. As a simple matter of fact, experience teaches that large numbers who try the process die morally under its poisonous action. In the case of disease we saw that this deliberate exposure to infection on the chance of recovery with immunity has been made illegal. It is too dangerous, both for the individual and the community. Too many will perish. Only those of high natural resistance will survive. The process is effective in eliminating the unfit, and it is Nature's method, but it is too cruel. In the same way, and for the same reason, the moral and religious law steps in, and says to the individual "Thou shalt not!"

Finally there comes the tremendous claim made by the founders of all moral systems—the claim that they can confer upon mankind an artificial immunity from the moral infection of temptation and the moral disease of sin. The claim is not put in these words, but, translated into modern science, and expressed in terms of immunity, that is what it means. The modern physician is not content to trust to the chance of his patient's recovery to make him immune. The risk is too great. The moral teacher likewise sees the danger of such a process. The physician urges upon his patient not to wait until he be exposed to infection, but to protect himself beforehand by acquiring an artificial immunity. The moral teacher takes the same line, and offers a method of treatment which he claims will confer upon the person an acquired immunity for a time. True, the effect is temporary. All artificial immunity is so, more or less. But the supply is inexhaustible, the process safe, the result certain.

Immunity from Alcoholism. To make all this perfectly clear we may take one concrete example—that of alcohol. Some people have a marked degree of natural inborn immunity from the temptation or the effect of alcohol. They constitute the great majority of the sober members of the population. They are sober because they are immune. If any habitually sober man imagines that he is so because of his strong efforts to struggle against the temptation of alcohol every hour of his life, he deceives himself. It is not so. The sober man who is at the same time honest will admit, if he thinks, that to him alcohol is no temptation. He is immune. The present writer has asked hundreds of sober men why they were so, and every one, after consideration, has admitted the truth of the above statement. To most of us, therefore, it is no credit to be sober, but it should be a matter of great thankfulness that we are naturally immune.

Of those who are naturally susceptible or who acquire a taste for alcohol, a certain number in time become immune. But it is after such an experience as few would care to risk. It is a test under which most succumb, and is far too dangerous to be made a routine process. All moral and religious teachers have clearly recognised this, and they therefore offer a method of acquiring immunity which they claim to be safe, speedy, and certain. They claim that the power of the influence which they prescribe is so strong that it will protect not merely from one, but from all moral infection. In this one point they go beyond anything that science has yet discovered in the sphere of infection disease; but in every other detail the offer which they make appears to be perfectly scientific and practical. It is the method which we ourselves adopt in dealing with our fellow-men. It is the only method by which man can become immune from all deleterious influences, mental, moral, or physical.

GAS, OIL, AND PETROL ENGINES

Group 24
PRIME MOVERS
10

Continued from page 6648

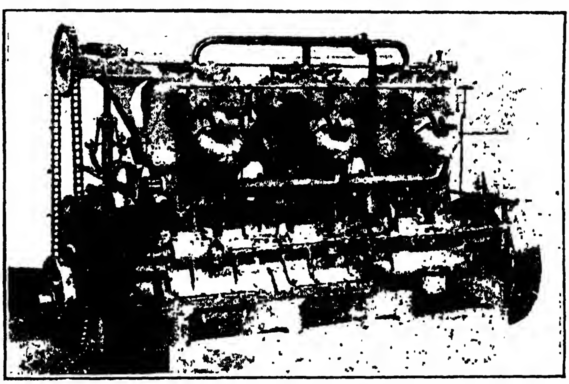
The Gas Engine. Cycles. Gases. Oil Engines. The Diesel. Petrol Motors. Thornycroft. Daimler

By JOSEPH G. HORNER

GAS, oil, and petrol engines are all classed as internal combustion engines, because the fuel is burned within the cylinder instead of in a boiler separate therefrom. Though the heat problems involved are similar to those of steam-engines, the practical working conditions are different in many details. In each case the effect of heat is expansion and pressure, but the pressure of the elastic fluid steam is not of so violent a character as that in the gas-engine. In the latter, an explosive mixture of gas with atmospheric air in certain definite proportions is made and ignited, and so exploded. The resulting heat is so intense that the cylinder would become rapidly overheated unless it were water-jacketed. This, of course, entails much loss of heat, and is exactly contrary to that which exists in steam-engine practice, in which the cylinder is jacketed to lessen escape of heat. Yet the heat efficiency of the gas-engine is greater than that of the steam-engine, because there is no loss consequent on the use of a steam-boiler, and the fuel is therefore used directly.

The term "gas" covers a wide range of product, from town's gas and producer-gas to blast-furnace waste and Mond gas. The only difference in the gas, and the oil and petrol engines, is that the first is all ready for use, and the two last have to be gasified.

Cycles. A cycle means the entire series of operations involved in the utilisation of a given charge from the period of its introduction to discharge or exhaust. The Otto cycle is that which is now nearly always used. It includes the drawing in of the gas and air into the cylinder, following behind one stroke of the piston, the compression of the mixed charge during the return stroke, and firing at the termination of the in-stroke. It is burnt and exploded in the next forward stroke. There is thus only one actual working stroke in four in an Otto single-acting engine; but further economy is ensured by governing on the hit-and-miss principle. The governor opens or closes the gas valve, responsive to the load on the engine. Most large engines, however, are now often governed in another way, by varying the volume of the gas admitted. The amount of compression possible varies with different gases from about 4 atmospheres to 10, being dependent on the proportion of hydrogen present. The larger the proportion of hydrogen, the less compression is possible. Ignition is effected by an electric spark, or by a red-hot tube.

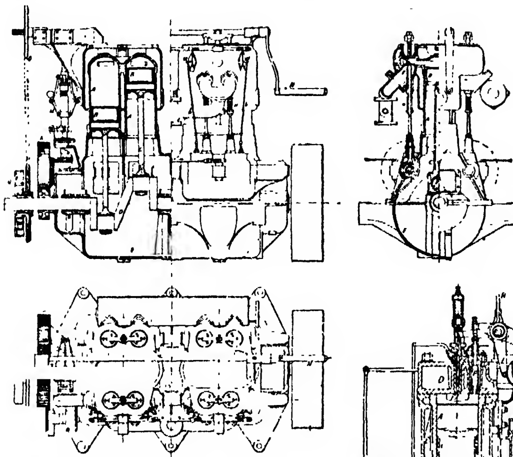


82. 78-B.H.P. PETROL ENGINE FOR MARINE USE
(John I. Thornycroft & Co., Ltd.)

Gases. The gases used vary much in calorific or heat-giving power. Town's gas alone was used in the early days of the gas-engine. It has a higher percentage of heat-giving power than any other; but its use has long been discarded for large engines in favour of gases lower in calorific power, but much cheaper. The calorific capacity of producer gas is only about one-fourth that of retort gas, that of Mond gas about the same, while that of blast-furnace gas is only about one-sixth. But the nitrogen in the latter takes the place of much of the air ordinarily required in retort gas, and hence the engine efficiency is higher than the calorific value of the gas alone would indicate. In the gas producers, fuel generally of a cheap and inferior kind is fed from a hopper to a brick-lined cylindrical vessel containing a grate. Air is fed by a fan, and carbonic oxide is formed, with nitrogen and other elements in various proportions, according as the method adopted is dry, or wet, or water-gas.

Blast-furnace Gas. Nothing has given so much impetus to the growth of the large gas-engine as the utilisation of blast-furnace gas. The first large engine of this kind exhibited was at the Paris Exhibition of 1900, being of about 600-h.p., which has been more than doubled since. As long as town gas or Dowson producer gas were the only sources available, engines of over 100-h.p. were rarely made. The space occupied by generating plant, and the cost, did not compare very favourably with the steam-boiler plant. In the development of these vast engines, the Cockerill Co., of Belgium, and some German firms led the way. The result is that these engines are now scarcely discernible from steam-engines in external appearance; they are double-acting, and the valves of the drop type resemble those of steam-engines. The hit-and-miss regulation is abandoned in favour of a governor-actuated cam, which regulates the amount of lift of the gas valve, besides which, an immense number of special details are included. At Oberhausen there are seven double-acting engines of this kind, four of which are 1,000-h.p. By designing engines tandem, with two, or four cylinders, the power is multiplied; so that there are engines of 2,000-h.p. and over at work, and there is no reason why from 5,000-h.p. to 6,000-h.p. should

not be made if required. In the early days of blast-furnace gas-engines, much trouble arose from the presence of dust and of tar. The dust is now readily got rid of, but the tar still causes trouble, lodging in the cylinder and causing the valves and piston rings to stick in their seatings.



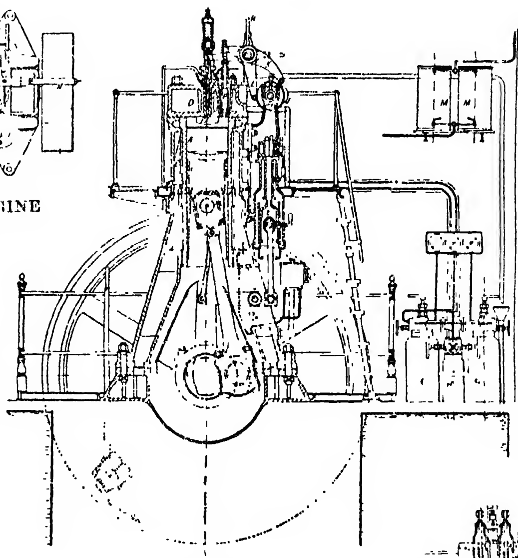
93. THORNYCROFT ENGINE

Oil-engines. These are gas-engines to which the fuel is supplied in the liquid form. Their value lies chiefly in isolated districts in which no power-gas is available. Ordinary petroleum is generally used. The oil is introduced in definite volume into a highly heated chamber—the vaporiser—along with a suitable supply of air. The mixture is then drawn into the working cylinder by the suction stroke. It is then compressed on the return or in-stroke, and ignited. The explosion gives the working stroke, and in the return stroke the products of combustion are exhausted, thus embodying the Otto cycle. The governor lessens the number of explosions when the engine is running light. In some engines the oil is sprayed and mixed with air before it is passed into the working cylinder to be compressed. In others the air is compressed in the vaporiser. The charge of oil and air when it enters the cylinder should have a temperature of from 170° F. to 300° F. About 1 lb. of oil is required per brake horse-power per hour. Petroleum suitable for engines should have a specific gravity of 0·8, and 150° F. its flash point. Cylinders are jacketed as in gas-engines. The thermal efficiency of oil-engines ranges between about 12 per cent. and 18 per cent., the latter being high. By thermal efficiency is meant the ratio of the actual work done by the engine at the brake (B.H.P.) in a given time to the total heat supplied per minute by the complete combustion of the oil required to do that work. Or,

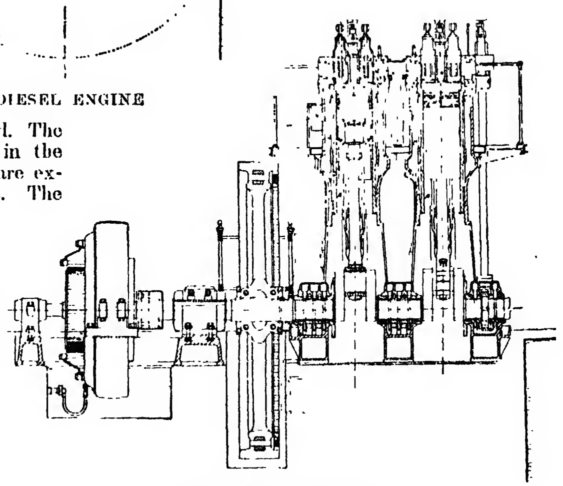
$$\text{Thermal efficiency} = \frac{\text{work done per minute}}{\text{heat supplied per B.H.P. per minute}}$$

One-horse power = 33,000 foot-pounds per minute, or 42·63 heat units. The heat unit is the quantity of heat required to raise the temperature of 1 lb. of water through 1° F., and is equivalent to 774 foot-pounds.

The Diesel Engine. This [94 and 95] is a remarkable type of oil-engine which has been developed rapidly of late years. The leading feature by which it is distinguished is the very high compression and temperature employed, from which various results follow. It operates upon the four-cycle principle. During the first stroke air alone is drawn into the cylinder at atmospheric pressure and temperature, and this charge of air only is compressed on the return stroke, to a pressure of about 32 to 35 atmospheres, or, say, 450 lb. to 500 lb. per square inch with a temperature of about 1,000° F. During the third or working stroke the oil fuel is gradually injected by means of an air jet at a pressure of about 800 lb. per square inch. The effect is to spray the oil very finely throughout the highly heated charge of air, with which it is ignited, in consequence of the high pressure present, no ignition apparatus being necessary. There is, therefore, no sudden explosion, such as that which occurs in the ordinary oil-engine,



94. DIESEL ENGINE

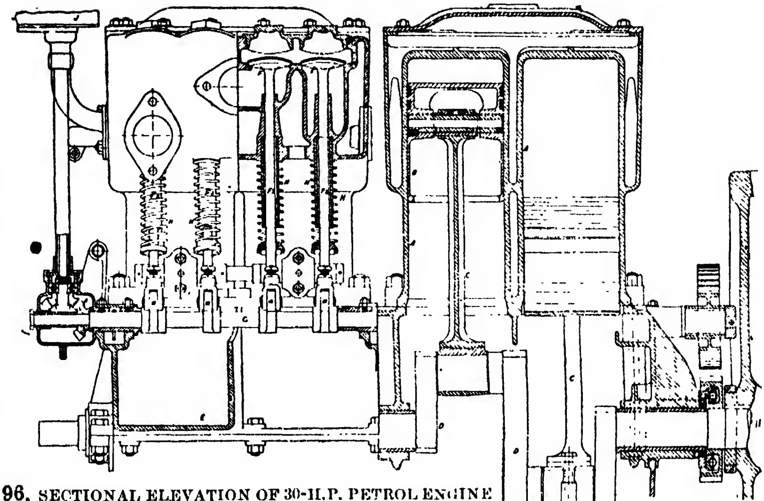


95. DIESEL ENGINE

but a gradual combustion and gradual expansion without shock. The fourth stroke exhausts the products of combustion.

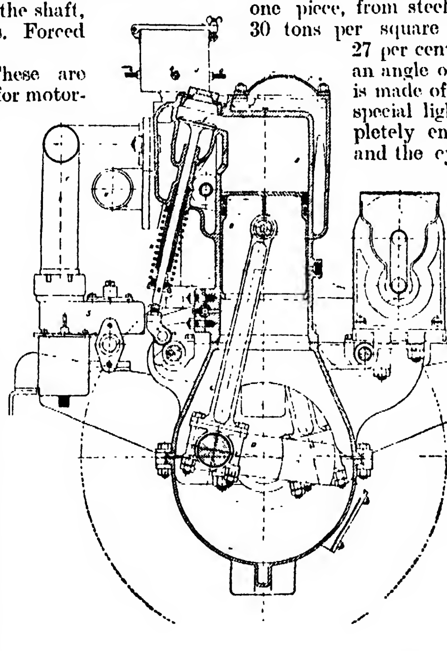
In the illustrations [94 and 95], which is an engine by the Vereinigte Maschinenfabrik Augsburg und Maschinenbaugesellschaft Nürnberg A.G., Augsburg, the following are the principal parts of the engine:

The cylinder A is fitted with a water-jacket B; the piston C is of trunk form; the engine cover D is at the head of the cylinder, and is also water-jacketed; E is the air pump; N is the fuel feed pump. The compressed air is stored in the vessels G, G, H, one of G being a reserve. The fuel is received from the filtering tanks M, M, and brought into the fuel valve F above the cylinder by means of the pump N. The other valves are the starting valve P, the exhaust valve O, and the air pump suction valve Q. By means of the handle R the reversing lever is placed in the starting position F. After opening the valve on vessel G the motor starts running. If it has reached the speed required for igniting the fuel, the reversing lever is placed in working position, and then the engine works with fuel and may be loaded at once. The valves are all operated by cam plates on the shaft, J, K and L being the levers. Forced lubrication is adopted.



96. SECTIONAL ELEVATION OF 30-H.P. PETROL ENGINE
(Daimler Motor Co., Ltd.)

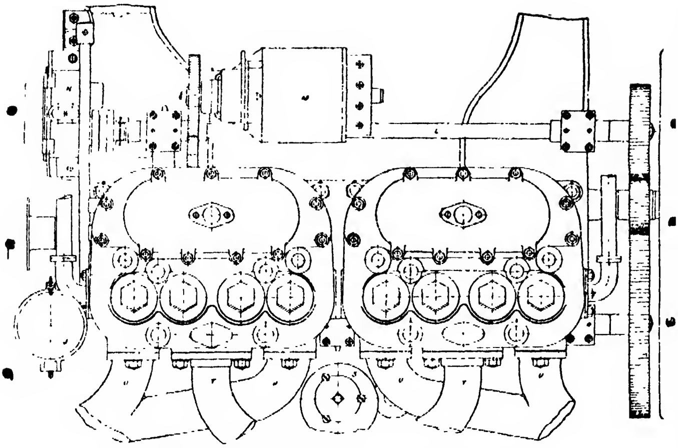
Petrol Motors. These are special types of oil-engines for motor-cars, launches, and other purposes, in which petrol, vapour and air form the combustible mixture. They are made in four and two-stroke cycle types. The first-named is the same as that already explained. In the second the operations are as follows: The mixture of petrol vapour and air is first drawn into the crank chamber, or into a separate pump cylinder. It is compressed to about 5 lb. per square inch, and is introduced into the cylinder at about the period of the termination of the out-stroke. It is compressed by the in-stroke, and is ignited by an electric spark. The charge expands and drives the piston outwards, and the products of combustion escape through ports in the cylinder walls. The two-stroke design has the advantage of simplicity of construction, but consumes more fuel than the four-stroke cycle does. The heat generated is probably about 1,800° F., which renders water-jacketing or air cooling necessary.



97. END SECTIONAL ELEVATION OF 30-H.P. ENGINE
(Daimler Motor Co., Ltd)

Figure 98 illustrates one of the petrol engines by Messrs. John I. Thornycroft & Co., Ltd., of Chiswick, for marine use. Many details which are not shown here may be observed in the photograph [92], of an engine of similar type, but having six cylinders. The drawing shows a 6 in. by 8 in. cylinder engine. In this, A indicates the cylinders, water-jacketed; B the trunk pistons, with spring rings; C the connecting rods, which are steel stampings; D the crankshaft, machined from one piece, from steel having a tensile strength of 30 tons per square inch, with an elongation of 27 per cent. The crankpins are set at an angle of 180°. The crank casing E is made of cast iron, or aluminium when special lightness is required. It is completely enclosed, is fitted with doors, and the cylinders are registered into and bolted on it. Lubrication of this engine is of the splash system, but a pump and forced lubrication is often adopted.

In front of the photograph [92], and at the lower right-hand end the carburetter is seen, with the air inlet and throttle leading to the supply pipes to the cylinders. The carburetter consists of a body in which the incoming air, as it is sucked by the motor, rushes past a nozzle, from which the petrol is drawn out in a spray and, volatilising, passes thence through the throttle. In F is the inlet pipe to the cylinder, and G is the inlet valve. The exhaust valves are on the opposite side of the cylinders (compare with the plan view). The valve rods H are actuated from the cam shafts J, operating hard steel rollers on the tappet shafts. These cam shafts are driven from the crankshaft through the gears K, K, from the smaller gear L on the crankshaft, and open and close the valves once for each two revolutions of the flywheel. The valves B are lifted by the cams against the pressure of the springs seen encircling the rods, which springs



98. PLAN OF 30-H.P. PETROL ENGINE

close the valves after the full of the cam has passed. From one of the cam shafts the governor M is driven through bevel wheels. The method of its connection with the throttle, on which it acts directly, is seen in the photograph. The method of firing is by means of a low-tension magneto system. The permanent magnets are seen at the left-hand end of the photograph, just below and in front of the governor. The lower ends of the magnets carry two pole-pieces. Within these there is a fixed armature, and between them a soft iron shield or sleeve rotates. The sleeve has two slots cut in it at opposite sides, leaving two open spaces of about 90°. The armature is wound with insulated copper wire, and the lines of force that cut the armature coils vary from nothing to maximum, and maximum to nothing twice in a revolution. Four sparks are thus made per revolution. In another type the armature rotates instead of the shield. The sparking plugs are screwed into the cylinders at *a*, close to the inlet chamber, connected with the magneto by the wires *b*. A contact-breaker placed close to each plug is operated by a cam and a vertical rod. N is the starting handle connecting its shaft with the crankshaft by pitch chain passing over wheels O, P. Q is the free-wheel clutch. It is composed of a pair of ratchets which are carried on the casing round the clutch, and which in its turn is connected to the crankshaft of the engine. The starting chain wheel is attached to the ratchet wheel, which engages with the ratchets in one direction only. When it is desired to start the motor, the starting handle, and consequently the chain wheel, is turned, and drives the crankshaft by means of the ratchet wheel and ratchets. As soon as the engine fires the crankshaft outruns the chain wheel, and centrifugal action causes the ratchets to fly out of contact with the ratchet wheel. The starting handle thus becomes stationary, and the ratchets being out of contact with the wheel, there is no noise caused by their rubbing over the teeth.

A 30-h.p. Daimler motor, designed for a car (Daimler Motor Co., Ltd., Coventry), is shown in **96, 97** and **98,** lettered as follows: A indicates the cylinders, B the pistons, C the connecting rod, D the crankshaft, and E the base chamber. S indicates the vaporiser, T the vapour pipe leading to the induction ports of the cylinders, and U the pipe for carrying away the exhaust gases.

It will be observed that the cylinders are cast in pairs, and water-jacketed. The connecting rods are of H section, and the crank chamber is cast in aluminium. The induction and exhaust valves—which are interchangeable—are indicated at F1 and F2 respectively, and are actuated by the cam shaft G and tappet and roller *a*, the spring H pulling the valve down on to its seating as the cam projection passes the roller *a*. The cam shaft is driven by the usual half-speed wheels. On the side of the cylinders, opposite to and running parallel with the cam shaft, is the lay shaft L, which drives the magneto M and the gear pump N. It may be mentioned that the magneto is fitted as an alternative source for the supply of current to the sparking plugs, and is entirely independent of the ordinary high-tension circuit with induction coil and accumulators as depicted in **99**, which illustrates the method of wiring; also the plan of the distributor case J with the cover removed, showing the block O, which is in contact with and rotates between the brushes P, and thereby makes and breaks the low-tension or primary current. The distributor block O is so designed that the distribution of the secondary or high-tension current to the insulated plugs Q, and thence to the sparking plugs R, synchronises with the opening and closing of the primary or low-tension circuit. The distributor case, which, under normal conditions, is stationary, can, for the purpose of advancing and retarding the timing of the spark, be rotated on its own axis through the required angle. The vertical shaft, to which the distributor block is keyed, is driven by means of bevel gears, K, K, off the end of the cam shaft. Ball bearings are fitted at each end of the vertical shaft. The approximate weight of the above-described engine is 6 cwt.

SOLUTION OF TRIANGLES

The Ambiguous Case. Worked Examples Illustrating the Four Cases. List of Text-books

By HERBERT J. ALLPORT, M.A.

44. Case Two of Solution of Triangles. Given one side and two angles, say a, B, and C. Since the three angles of a triangle equal 180°, we have $A = 180° - B - C$.

Again, $\frac{\sin A}{a} = \frac{\sin B}{b}$, so that $b = \frac{a \cdot \sin B}{\sin A}$.

Similarly, $c = \frac{a \cdot \sin C}{\sin A}$.

These two equations give the values of b and c.

Adapting these formulæ to the use of logarithms, we have

$$\log b = \log \frac{a \cdot \sin B}{\sin A}$$
$$= \log a + \log \sin B - \log \sin A$$
$$= \log a + (L \sin B - 10) - (L \sin A - 10)$$

or, $\log b = \log a + L \sin B - L \sin A$.

Similarly,

$$\log c = \log a + L \sin C - L \sin A.$$

45. Case Three of Solution of Triangles. Given two sides and the included angle, say b, c, and A. We have $B + C = 180° - A$, which gives the value of $(B + C)$. Then, from Article **40**,

$$\tan \frac{B - C}{2} = \frac{b - c}{b + c} \cdot \cot \frac{A}{2}.$$

This gives the value of $\frac{B - C}{2}$, and therefore of $(B - C)$. Having obtained the values of $(B + C)$ and $(B - C)$, the values of B and C can be found.

Finally, since $\frac{a}{\sin A} = \frac{b}{\sin B}$, or $a = \frac{b \cdot \sin A}{\sin B}$, we obtain the value of a.

To arrange the method for logarithmic work we proceed thus:

$$\tan \frac{B - C}{2} = \frac{b - c}{b + c} \cdot \cot \frac{A}{2}.$$

$$\therefore \log \tan \frac{B - C}{2}$$
$$= \log (b - c) - \log (b + c) + \log \cot \frac{A}{2};$$

or, adding 10 to each side of the equation,

$$L \tan \frac{B - C}{2} = \log (b - c) - \log (b + c) + L \cot \frac{A}{2}.$$

And, as in Article **44**, from $a = \frac{b \cdot \sin A}{\sin B}$, we get

$$\log a = \log b + L \sin A - L \sin B.$$

46. Case Four of Solution of Triangles. Given two sides and the angle opposite one of them, say b, c, and B.

Since, $\frac{\sin C}{c} = \frac{\sin B}{b}$,

$$\therefore \sin C = \frac{c \cdot \sin B}{b}. \quad . \quad . \quad . \quad (1)$$

C can be found from this equation. Then, having found C,

$$A = 180° - B - C.$$

The value of a is found, as in the last article, from the formula $a = \frac{b \cdot \sin A}{\sin B}$.

47. The Ambiguous Case. In the case considered in Article **46**, the solution of equation (1) gives the value of the *sine* of C. Now, when C is an angle of a triangle, and the value of *sin* C is known, C itself may have *two* values, one of them being less than 90°, and the other being between 90° and 180°.

Hence, there *may* be *two* triangles in which b, c, and B have the given magnitudes. Whether this is so may be decided as follows:

1. If B (the given angle) is *greater than* 90°, C must be *less than* 90°, since any two angles of a triangle must be together less than two right angles. Therefore, when B is greater than 90°, there is only one triangle which satisfies the given conditions.

2. When B (the given angle) is less than 90°, four things have to be considered.

(i.) Is b less than $c \cdot \sin B$? If so, then, since $\sin C = \frac{c \cdot \sin B}{b}$, the value of sin C is greater than 1, which is impossible [Art. **15**]. In this case there is *no* triangle which satisfies the given conditions.

(ii.) b may be *equal* to $c \cdot \sin B$. We should then have $\sin C = 1$, and therefore $C = 90°$. In this case, then, there is only *one* triangle.

(iii.) If b is greater than $c \cdot \sin B$, but *less than* c, then B is less than C [Geometry, *Prop.* 21], and therefore C may be acute or obtuse. Hence, C may have either of the values found from the equation $\sin C = \frac{c \cdot \sin B}{b}$, and there will then be *two* triangles satisfying the given conditions. This is the *ambiguous case* in the solution of triangles.

(iv.) If b is equal to or greater than c, then B is equal to or greater than C. Hence, C must be an acute angle, and therefore there is again only one triangle satisfying the given conditions.

48. We shall conclude with examples illustrating each case in the solution of triangles.

Example 1. Given that $a = 40$, $b = 51$, $c = 43$,

$$\log 2 \doteq \cdot 3010300, \quad \log 3 = \cdot 4771213,$$
$$\log 67 = 1 \cdot 8260747.$$
$$L \tan 24° \, 44' \, 13'' = 9 \cdot 6634464, \text{ find A.}$$

Here, $a+b+c=40+51+43=134$.

$\therefore s=67,\ s-a=27,\ s-b=16,\ s-c=24$

$$\therefore \text{L}\tan\frac{\text{A}}{2}-10$$
$$=\tfrac{1}{2}\{\log 16+\log 24-\log 67-\log 27\}$$
$$=\tfrac{1}{2}\{\log 2^4+\log 3+\log 2^3-\log 67-\log 3^3\}$$
$$=\tfrac{1}{2}\{4\log 2+\log 3+3\log 2-\log 67-3\log 3\}$$
$$=\tfrac{1}{2}\{7\log 2-2\log 3-\log 67\}$$
$$=\tfrac{1}{2}\{2{\cdot}1072100-{\cdot}9542426-1{\cdot}8260747\}$$
$$=\tfrac{1}{2}\{2{\cdot}1072100-2{\cdot}7803173\}$$
$$=-\tfrac{1}{2}\{{\cdot}6731073\}=-{\cdot}3365536=\bar{1}{\cdot}6634464.$$

$$\therefore \text{L}\tan\frac{\text{A}}{2}=9{\cdot}6634464$$
$$=\text{L}\tan 24^\circ\,44'\,13''.$$
$$\therefore \text{A}=2\times(24^\circ\,44'\,13'')=\underline{49^\circ\,28'\,26''.}$$

Example 2. In the triangle ABC, the base AB is 1,000 ft. long, and the angles at A and B are 31° 20′ and 125° 19′ respectively. Find the length of AC.

We are given A, B, and c.

First, $\text{C}=180^\circ-31^\circ\,20'-125^\circ\,19'$
$=23^\circ\,21'.$

Again,

$$\log b=\log c+\text{L}\sin\text{B}-\text{L}\sin\text{C}$$
$$=\log 1000+\text{L}\sin 125^\circ\,19'-\text{L}\sin 23^\circ\,21'$$
$$=\log 1000+\text{L}\sin 54^\circ\,41'-\text{L}\sin 23^\circ\,21'$$
$$=3+9{\cdot}9116739-9{\cdot}5980754$$
$$=3{\cdot}3135985$$
$$=\log 2058{\cdot}725.$$

Thus, $\text{AC}=\underline{2058{\cdot}725\text{ ft.}}$

Example 3. Two sides of a triangle being 2265·4 ft. and 1779 ft., and the included angle being 58° 17′, find the remaining angles of the triangle.

Suppose $b=2265{\cdot}4$, $c=1779$, and $\text{A}=58^\circ\,17'$.

Then, $\text{B}+\text{C}=180^\circ-58^\circ\,17'=121^\circ\,43'.$

Again, $\text{L}\tan\dfrac{\text{B}-\text{C}}{2}$

$$=\log(b-c)-\log(b+c)+\text{L}\cot\frac{\text{A}}{2}$$
$$=\log 486{\cdot}4-\log 4044{\cdot}4+\text{L}\cot 29^\circ\,8'\,30''$$
$$=2{\cdot}6869936-3{\cdot}6068541+10{\cdot}2537195$$
$$=9{\cdot}3338590$$
$$=\text{L}\tan 12^\circ\,10'\,21''.$$

$$\therefore \frac{\text{B}-\text{C}}{2}=12^\circ\,10'\,21''$$

and $(\text{B}-\text{C})=24^\circ\,20'\,42''.$

But $(\text{B}+\text{C})=121^\circ\,43'.$

$\therefore 2\text{B}=146^\circ\,3'\,42''$

and $2\text{C}=97^\circ\,22'\,18''.$

Hence, $\left.\begin{aligned}\text{B}&=73^\circ\,1'\,51''\\ \text{C}&=48^\circ\,41'\,9''\end{aligned}\right\}$ *Ans.*

Example 4. The lengths of two sides of a triangle are 5374·5 ft. and 1586·6 ft.; the angle opposite to the shorter side is 15° 11′. Calculate the other angles of the triangle, or of the triangles, if there are two.

Suppose $b=1586{\cdot}6$ ft., $c=5374{\cdot}5$ ft., and $\text{B}=15^\circ\,11'$. Then,

$$\text{L}\sin\text{C}=\log c+\text{L}\sin\text{B}-\log b$$
$$=\log 5374{\cdot}5+\text{L}\sin 15^\circ\,11'-\log 1586{\cdot}6$$
$$=3{\cdot}7303381+9{\cdot}4181495-3{\cdot}2004674$$
$$=9{\cdot}9480202$$
$$=\text{L}\sin 62^\circ\,31'\,23''.$$

$\therefore \text{C}=62^\circ\,31'\,23''$,

or $180^\circ-62^\circ\,31'\,23''=117^\circ\,28'\,37''.$

And b is less than c, therefore both these values are admissible.

Thus there are two triangles.

(i.) $\text{B}=15^\circ\,11'$, $\text{C}=62^\circ\,31'\,23''$, so that $\text{A}=102^\circ\,17'\,37''$.

(ii.) $\text{B}=15^\circ\,11'$, $\text{C}=117^\circ\,28'\,37''$, $\text{A}=47^\circ\,20'\,23''$.

Example 5.

Given that $\text{C}=52^\circ\,10'$, $b=643$ yd., $c=872$ yd., find the other angles.

$$\text{L}\sin\text{B}=\log b+\text{L}\sin\text{C}-\log c$$
$$=\log 643+\text{L}\sin 52^\circ\,10'-\log 872$$
$$=2{\cdot}8082110+9{\cdot}8975162-2{\cdot}9405165$$
$$=9{\cdot}7652107$$
$$=\text{L}\sin 35^\circ\,37'\,7''.$$

$\therefore \text{B}=35^\circ\,37'\,7''$,

or, $180^\circ-35^\circ\,37'\,7''=144^\circ\,22'\,53''.$

But b is less than c, therefore B must be less than C. Hence, the second value found for B is inadmissible.

Thus $\text{B}=35^\circ\,37'\,7''$, and

$\text{A}=180^\circ-35^\circ\,37'\,7''-52^\circ\,10'=92^\circ\,12'\,53''.$

The above examples, with the exception of Example 1, are worked direct from the Tables of Logarithms. As already mentioned, the method of finding the logarithm corresponding to a given number or trigonometrical ratio, or the number or angle corresponding to a given logarithm, is explained in the book of logarithms.

49. Text Books. For the student who wishes to go further into Mathematics the following textbooks can be recommended.

Algebra.—"A Treatise on Algebra," by Charles Smith (7s. 6d. Macmillan & Co.); "Higher Algebra," by Hall and Knight. (7s. 6d Macmillan & Co.)

Geometry. "A School Geometry." Hall and Stevens. (4s. 6d. Macmillan & Co.)

Trigonometry.—"Plane Trigonometry." Todhunter and Hogg. (5s. Macmillan & Co.)

Conic Sections.—"Geometrical Conics," 6s., and "Conic Sections," 7s. 6d., both by Charles Smith. (Macmillan & Co.)

"Differential Calculus for Beginners." Joseph Edwards. (4s. 6d. Macmillan & Co.)

"Integral Calculus for Beginners." Joseph Edwards. (4s. 6d. Macmillan & Co.)

CABLE-MAKING AND LAYING

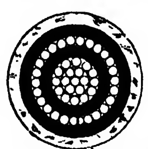
Concentric and Three-core Cables. Methods of Joining Cables. Systems of Cable Laying

Group 10
ELECTRIC CABLES
2

Continued from page 6548

A CONCENTRIC cable [4] consists of a prime central conductor, an insulation covering, a second conductor outside the insulation, a second insulation on top of the second conductor, and a protective covering. The second conductor is in the form of a copper wire ring, which is concentric with the prime conductor. The insulation in this make of cable is usually of paper or jute. The reason for this is that the second conductor could not be well applied on a soft indiarubber insulation before vulcanisation, because it might cut through the plastic substance and cause a fault. Further, if the first insulation were vulcanised before the second conductor were added, the second insulation would have to be vulcanised, and while this was being done the first insulation would be vulcanised again. This would destroy all the good properties of the first covering, and cause it to crack when bent.

Making Concentric Cables. In the making of concentric cables, the first process is the making of the central stranded conductor by means of the stranding machine, as already mentioned. The conductor is taken from the stranding machine to the paper-lapping machine, where it receives a covering of several layers of strong manilla paper tape. This is applied by being spirally wrapped round the conductor much as though the tapes were wires being stranded round the core.



4. CONCENTRIC CABLE—LEAD COVERED

Each layer of paper is wrapped on in reverse spiral, for the reason stated, with rubber strips. The paper-covered core is now placed in a hot-air chamber, heated to about 250°, to drive out all moisture. Since the paper will again absorb moisture from the atmosphere if left about, it is at once taken to the tanks containing a special hot resinous compound. The paper is thoroughly impregnated with this compound until it is practically waterproof. At the same time, the compound adds a little to the better insulation of the cable. From the tanks the cable is again taken to the stranding machine, where it receives its second conductor. This requires careful application, since, when it is on, the wires forming it must have a combined sectional area equal to that of the prime conductor, because both will have to carry the same amount of current with the same amount of resistance. If the sectional area differed, the smaller conductor would offer more resistance than the greater to the passage of the same amount of electricity. This would cause waste of current and more heat in the circuit, therefore both conductors should be of the same sectional area. The second insulation is now applied by the wrapping, drying, and impregnating processes as before.

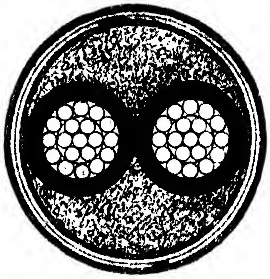
Lead Covering. With a moisture-absorbing material like paper a waterproof covering is necessary; therefore, as the cable comes out of the compound tanks for the second time it is taken to the hydraulic lead press to be encased with a lead sheathing. The method of applying this has been much discussed among cable-makers, some preferring to put on the lead at a high temperature with low pressure, and others at a lower temperature with high pressure.

In the former method, the lead is very liable to small air holes, or pores, and the thickness of the sheathing is not usually the same all the way round. In the second method, owing to the increased pressure, porosity is less likely to occur, and the thickness of the covering is more smoothly and evenly maintained; hence the high pressure process is now becoming general. At the hydraulic press the cable passes through the centre of a die, through which the lead is forced at the same time under very great pressure and at a temperature well below melting point. This gives the cable a closely-fitting protective sheathing against dampness and mechanical injury. With the lead covering on, the cable is ready for testing. In connection with these paper-insulated cables, the great difficulty is to prevent dampness getting to the insulation, because dampness not only conducts electricity, but also quickly rots the paper and causes a fault. When a fault occurs, there is no telling what may happen, so that it behoves makers to see that the cable is sound before it leaves the works.

Testing Lead-covered Cables. The testing of lead-covered cables is rather difficult to conduct in a satisfactory manner. The cable is first placed in water-tanks, and left there for about twenty-four hours, the ends being carefully kept out of the water, because they are not fully protected against dampness. When the test for insulation resistance is made, the ends are carefully prepared to prevent surface leakage by being coated over with an insulating compound. Both the waterproof and the insulation resistance tests are very similar to those for indiarubber insulated cables. It will be noticed that the concentric cable is not tested as soon as the insulation is applied, as the single cable was, and the reason for this will be readily understood when it is remembered that the chief idea right through the process of making the cable is to prevent dampness in the paper.

The unsatisfactory part of the testing when the lead covering is on is this: owing to the method of application, there is always the possibility of weak places occurring in the lead. These will withstand the tests when the cable is newly made and before it has been wound many times on a drum, but very soon after it comes to be wound and unwound in the process of laying, the weak places break down, and when next the electricity is sent through there is a fault shown. After the testing the cable is ready for use. Since lead soon decomposes when laid in the ground, this class of cable is usually laid in conduits. The concentric cable, having two conductors, may be used alone.

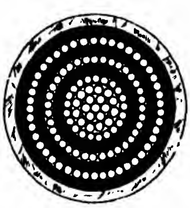
Twin Cable. This is called a twin cable [5] because it has two similar insulated conductors bound together under one protective covering. The two conductors are stranded separately at the machine, and each is separately insulated by indiarubber, bitumen, or paper.

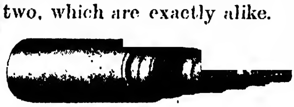


5. TWIN CABLE—DOUBLE-STEEL TAPE ARMOURED

As the conductors are usually small in twin cables, they can generally receive their insulation, if of indiarubber, at the longitudinal machine. If bitumen or paper is used, the insulation is applied by the wrapping process. After receiving the insulation of indiarubber, the cables are tested in a manner similar to the single indiarubber cable. Up to the testing process the two conductors are treated as separate cables, but from this point they become as one. If they withstand the tests satisfactorily, they are placed side by side and closely packed round with broken jute, usually impregnated with resinous or tarry compounds. A stout jute braid is then applied round the packing to keep it tightly in its place, and to make a solid core around which a lead covering or wire armouring may be placed. Before the armouring is applied, the braided cable is passed through the serving tanks to receive its covering of compound, which acts as a preventive against dampness. The lead covering is also put on for this purpose, but it further acts as a mechanical protection.

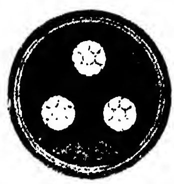
Triple Concentric Cable. This [6] is so called on account of the three concentric conductors which are enclosed within its armouring. It consists of a central conductor, a first layer of insulation, a second conductor in the form of a ring, a second layer of insulation outside the ring, then a third conductor, again in the form of a ring of copper wire, and a third insulation. As the insulation is usually of paper, for the reasons stated for the concentric cable, the usual protective covering is the waterproof lead sheath applied by pressure. The stranding of the conductors, the wrapping of the insulation, and the pressing on of the lead are all done in the manner as described for the concentric cable. If the triple concentric cable is to be used for a three-wire system, the outer conductor is usually made only one-half the sectional area of either of the other two, which are exactly alike.

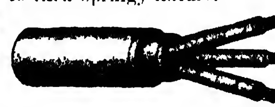




6. TRIPLE CONCENTRIC CABLE—LEAD COVERED

Three-core Cables. This cable [7], as the name implies, has three cores or conductors, each of which is separately stranded and insulated. All three are then bound together within one armouring. A sample of the three core cable before the writer is insulated with bitumen. To prepare this substance for insulation purposes, it must go through a thorough refining process. Much difficulty was at one time experienced in getting this material into such a condition that it was neither so brittle as to crack when bent nor so soft as to allow the heavy conductor to become decentralised when insulated with it. After the refining process the bitumen is compounded with chemicals, one of which is sulphur, and rolled into thin sheets. These are cut into narrow strips, which are wrapped spirally round the conductor, after a lapping of paper or indiarubber-covered cotton tape has been applied on the copper to prevent the sulphur in the bitumen from tarnishing it. The process of vulcanisation is the same as for indiarubber, and it is done for the purpose of adding strength and flexibility to the compound. Each conductor is generally of the same size, and insulated with the same thickness of material. When the insulation is vulcanised, the three cores are placed together and tightly packed round with jute soaked in oily or bituminous compound. A strong braid surrounds the packing, and on the outside of this the armouring is placed. This may take the form of galvanised iron wires, steel tapes, or lead sheathing. If steel tapes are used, they are applied by the steel taping machine and laid on in two spiral layers. The second layer is wound over the joints of the first, so that there is no joint showing right through the steel covering. Steel tapes are an excellent form of mechanical protection, as they are flexible and will withstand a lot of rough treatment without injuring anything underneath them. A covering of strong braid is usually placed over the steel tapes to protect them from rust, and to help to keep down the strain due to their springy nature.





7. SEVEN-STRAND THREE-CORE ARMOURED CABLE

Joining Cables. In the above descriptions only single lengths of cable have been dealt with. When a long cable is required, several of these lengths have to be joined together. The joining operation is very difficult, and much care must be taken in order to make a sound job. In the making of a joint the considerations to be borne in mind are that the joint should offer a resistance as near as possible to that of any other part of the conductor, the insulation about the joint should be as sound as any other portion of the cable, and the joint should be strong enough to withstand a certain amount of rough usage which it is sure to receive when being laid. The method of making the joint varies somewhat with the style of cable being joined. A common way of fastening together two lengths of small size cable (say, nineteen strand) is by what is known as the *married joint* [8]. To make this the conductors are stripped of their insulation for a short distance from the ends about to be joined. The bare conductors are then bound round with a few turns of thin copper binding wire at the place where the insulation ends. This is to keep the strands in place while the outer wires are bent back so as to disclose the central strands of seven wires. These are soldered up solid for some distance and then filed into a long bevel so that when placed together there will be a fairly large surface of each in contact with the other. The two ends are then held together while they are tightly bound with binding wire. The joint is then

soldered over and filed down smooth. The wires should be thoroughly cleaned before joining so that the solder will run well on them. The outer wires. which have been bent back, are now cut off at suitable lengths, alternate ones of each conductor being cut long and short. These are then butted together so that a long wire from one side butts against a short one of the other, and molten solder is poured over the joints, after binding wire has been wrapped over them. Figure 8 shows this joint.

The solder is filed down to smoothness so that there will be no sharp projections which might pierce the insulation. The reason for cutting off the outer wires in alternate long and short lengths is to avoid the overlapping of the wires and to make the finished joint as nearly as possible the same thickness as any other portion of the conductor. If the conductor is a very small one (say, of only seven wires), it is usually joined by one joint in a similar manner to the central strand as described above.

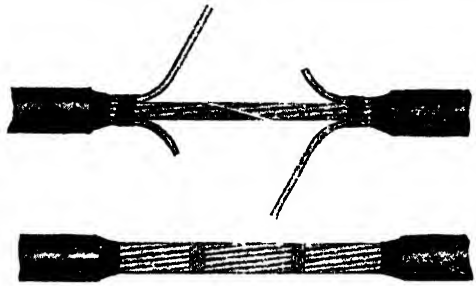
The Telescopic Joint. Another simple way of joining small cables is by the tel[illegible]pe joint as shown in 9. To make this th[illegible]conductors are stripped of their insulation for a short distance and then bound with wire as before. The outer wires of one conductor are then cut off at the binding, and the inner strand of the other is cut off at its binding. The outside wires, B, now remaining are laid up in position again so that they form a hollow cylinder into which the projecting central strand, A, of the first conductor, after being soldered up solid, is inserted. The end of the hollow cylinder touches the binding at which the outer wires were cut off. The whole joint is tightly bound with wire, and then soldered over and filed down smooth, after which it is ready for insulating.

In the concentric cable the inner conductor is joined by the single or married joint, according to size, and then insulated, the outer wires, or the second conductor, having been turned back out of the way. A sleeve of clean copper is usually placed over the joint on the outside of the first insulation, and on the top of this sleeve the second conductor is married, bound, and soldered as mentioned before. In joining concentric cables great care must be used so that the first insulation shall not be damaged in any way during the process of joining the second conductor. The second insulation is applied and then the protective covering.

Joint Boxes. Large cables are usually joined in specially made joint boxes filled up solid with compound to make them watertight and to improve the insulation.

When joint boxes are not used the insulation of the joints in cables is a very difficult matter, as will be readily understood when it is stated that these are the places in which the conductor will offer most resistance and consequently generate most heat. Further, the insulation will have to be tightly and soundly applied without any of its properties being impaired in any way. There are two ways of re-insulating the joints in indiarubber-covered cables; one by means of pure indiarubber, and the other by vulcanising indiarubber. The pure indiarubber joint is made by stripping back the tapes and braids so that they will be clear of the part to be reinsulated. When the indiarubber is thick enough the surface which has been exposed during the making of the copper joint should be trimmed down to the conductor in a long bevel.

This will expose a new, clean surface, to which the pure indiarubber strip about to be applied will stick better. If the copper joint is clean and smooth, the pure indiarubber strip is wrapped tightly and evenly round it, and over the bevelled surfaces, until a thickness equal to, or slightly greater than, that of the old covering is obtained. Strong tapes are then soaked in compound and tightly wrapped over the strip, and for a short distance over the original braiding. The whole joint is then

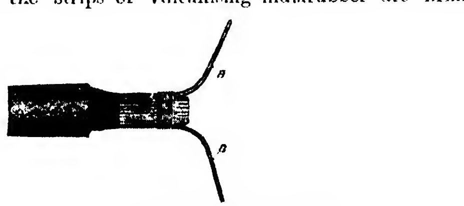


8. MARRIED JOINT

painted over with resinous, water-resisting compound. When the indiarubber insulation is not thick enough to be bevelled down, the new rubber may be lapped for about an inch or so over the old, which ought first to be well scraped and cleaned to remove all grease and dirt. This kind of reinsulation of joints answers all practical purposes in indoor low-pressure circuits where little moisture penetrates and little heat is generated.

Joining Cables Out of Doors. The making of a vulcanised indiarubber joint out of doors requires special apparatus, since it is practically impossible to carry about with one a steam generating plant and vulcanising pans. The molten sulphur bath is probably the most satisfactory portable vulcaniser for outside work. The bath may consist of a strong, cylindrical box, made in halves, and flanged so that they may be bolted together to enclose the joint. The upper half contains a hole through which the molten sulphur is poured, and through which a thermometer is placed so that the temperature of the sulphur can be read. The bottom half contains a tap, through which the sulphur is run out after the process is over. When the box is screwed up with the joint inside, the openings through which the cable passes are packed with common rubber to protect the insulation from the heated flanges.

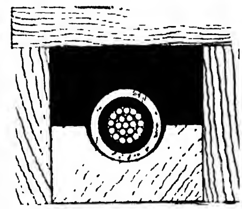
The preparation of the joint for the insulation is similar to that described above. When the bevelled edges have been cleaned, a lapping of pure indiarubber strip is tightly applied so that it just overlaps the thin edge of the bevel. On the top of this the strips of vulcanising indiarubber are firmly



9. TELESCOPE JOINT

wrapped until t[illegible] insulation about the joint is the same diameter as any other portion of the cable. The tightness and evenness of wrapping are essential to prevent small air spaces being left between the layers of insulation. A spiral wrapping of indiarubber-covered tape is placed over the vulcanising

rubber, and in order to keep the insulation in shape, and under pressure, a piece of sheeting is tightly rolled over the tape so as to form a longitudinal seam. On this a spiral wrapping of strong unprepared tape is applied. The sheeting and unprepared tape merely act as a mould while the joint is being vulcanised. As soon as the process is over both are removed. The sulphur is melted over the fire used for heating the soldering irons, and is poured through the top hole in the box. The temperature is maintained by placing spirit lamps under the box. It is advisable to heat the box first so that the temperature of the sulphur will not be greatly diminished when it comes into contact with the metal. After the sulphur has been kept at the proper temperature for the requisite time, it is run out, the box is unbolted, and the joint allowed to cool. The operation is over. A rough test for the degree of vulcanisation may be made by pressing the indiarubber, when cool, with the thumbnail. If this leaves no mark, the rubber may be considered to be correctly cured. If a mark is left the indiarubber is probably under-vulcanised, and if the substance feels hard and solid so that the nail makes no impression, over-vulcanisation has probably occurred. The vulcanised joint is protected by strong tapes and braid, which overlap for a short distance the original braid on the cable. Joints in bitumen-insulated cables are made in a similar manner to those described above, but the paper cables are more commonly joined in special joint boxes, which are watertight and take the place of lead covering.



10. SOLID SYSTEM OF CABLE LAYING

Testing Joints. When the joints are completed, they should be tested to see that their insulation resistance is not much different from that of an equal length of continuous cable. There are several ways of testing joints, but a simple and effective one is known as the accumulation method. The joint to be tested is placed in water contained in a trough which is thoroughly insulated by being raised from the ground on blocks of insulating material.

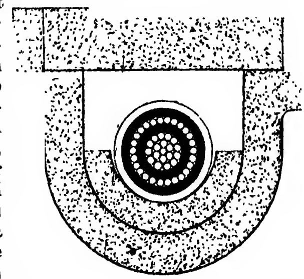
The trough should be tested before proceeding with any other tests. The length of cable containing the joint is connected to one pole of a battery, the other pole of which is connected, through a condenser, to the water by a wire, which is not allowed to touch the cable. The current passing through the insulation of the joint escapes through the water and along the wire to the condenser. This is then disconnected from the trough and connected to a galvanometer, through which the condensed or accumulated current passes, and gives a deflection. The joined length of cable is removed and a continuous piece substituted; the condenser is again connected with the trough and again collects the current passing through the resistance of the cable under test. The battery is kept on for the same time both cases. The second accumulated current sent through the galvanometer as before, and if the deflection obtained in the second case varies but slightly from that of the first, the joint may be considered satisfactory.

The trough may be tested by passing a currens through an electrometer until a steady deflection it obtained. The battery is removed and the electrometer connected to the trough. A decrease in the deflection of the instrument takes place, but if this decrease is only very slight, the trough is sufficiently well insulated for testing purposes.

Cable Laying. When the joints are tested and found sound the finished cable is ready for laying. The question of whether the cable should be laid underground or overhead is soon decided. In England the only method allowed in any of the large towns is the underground system, although under certain circumstances, especially for the transmission of electricity over long distances, the overhead lines may have decided advantages. Overhead wires are chiefly confined to outlying mining districts. There are many in South Wales. The several ways of laying cables underground may be grouped into two classes: (1) the "built-in," or "solid" system and (2) the "drawn-in" system. Figure **10** shows a lead-covered cable laid on the solid system, and **11** shows a cable laid in a conduit in the "drawn-in" system.

Access to built-in cables, when once they are laid, can be made only by opening up the ground, whereas in the drawn-in system, the cables, lying as they do in conduits, may be easily withdrawn into the nearest surface box for inspection. Greater mechanical protection is required in the "solid" method than in the "drawn-in." This is because the cables in the solid system are sometimes laid in the ground direct [12]. The armouring may consist of steel tapes, or iron wires, or the cables may be laid in troughs of wood or iron, filled up solid with compound. Sometimes broad tiles are placed just above the cables to give warning to workmen when opening the ground that the cable is at hand. Precautions are then taken that the pick or spade is not sent through the cable's insulation. In these troughs a good plan is to lay the cables on small bridges of wood, as shown in **10**, before filling up with the compound or asphalt.

Whichever of these plans is adopted, the cables must be laid while the ground is open, and this is a great inconvenience to traffic if the laying happens to be in a very busy thoroughfare. Further, the road authorities allow only a certain length of trench to be open at one time, and this is often a hindrance to rapid laying. When a length of trench is prepared, the drum containing the cable is mounted on a trolley and wheeled along the side of the trench so that it pays off the cable, which is laid in place in the trough. Hot compound is then poured over it. The trench is filled up, and the surface repaved.

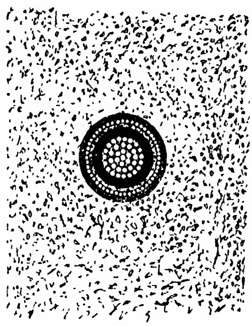


11. CONCENTRIC CABLE LAID IN STONEWARE CONDUIT

Drawn-in System of Laying. In the "drawn-in" system it is not necessary to go to the expense of strongly armouring the cables because they are provided with mechanical protection by the conduits into which they are drawn. The pipes or conduits are placed in the ground before the cables are drawn into them, and when once they are in position the ground need not again be opened. For the purpose of drawing the hauling line through the conduits, a wire is threaded through each section

of them, as they are laid, and it is fastened in the surface boxes. When the conduits are laid, the drum containing the cable is conveniently placed on an axle near the mouth of a surface box, and the end of the cable is connected, by a smooth, strong, fastening, to the hauling line, which is then drawn through the conduits by the wire left for that purpose. The rope is then used for drawing in the cable. The length of cable which may be drawn in at one hauling depends partly upon the weight of the cable but chiefly upon the straightness of the condu'ts about to be entered. In town work the lengths are usually short on account of the numerous sharp bends encountered. When a bend is reached, a length of cable, sufficient to reach to the next surface box, is drawn through and laid on the ground in long loops. The hauling rope is drawn on as before, and then the loops of cable gradually disappear into the conduits. The reason for raising the length of cable to the surface at the bend is to avoid the friction and extreme tension which would arise from the cable being drawn round a sharp corner. Even in straight lengths of conduit the friction is very great, and to reduce this as far as possible a coating of whiting is often applied, as a lubricant, to the cable. Sometimes a chain is drawn through the pipes to clear away any obstacles which might increase the friction or tension on the cable that follows. If the conduits are smooth to begin with, and these precautions are taken against friction, the possibility of damage to the cable during the drawing-in is reduced to a minimum.

Conduits. The cost of conduits [illegible] large-sized cables are laid, a separate way is usually provided for each one, although smaller sizes may be drawn in in pairs. This question of cost has led many people to turn their attention to the manufacture of cheaper kinds of pipes which can be readily joined together. Brick culverts are rarely used now because they take up much space underground, they occupy a long time in building, and are very costly. Earthenware conduits, with two or three cable-ways, can be laid much more quickly and cheaply, and they are now manufactured in a special way so that the joints can be easily made. The disadvantage of earthenware pipes is that they are very liable to fracture, and on account of this other kinds are sometimes substituted.



12. WIRE-ARMOURED CABLE LAID DIRECT IN THE GROUND

Bituminous concrete conduits are often used because they are fairly cheap. They are made in blocks with two or more passages, and are joined together by inserting short mandrels in each passage of two blocks while hot bituminous compound is poured into the joint and allowed to cool. When the mandrels are withdrawn the compound has formed a joint between the two blocks, and the mandrils have kept clear the passages through which the cables will be drawn. Cast-iron pipes are extensively used in connection with Post Office cables, as they have been found to be the most satisfactory.

Considerations in Laying. In deciding at any place whether the cables shall be laid by the "solid" or "drawn-in" systems, considerations are given chiefly to the cost of the cables and conduits. If the "built-in" cables are laid in iron troughs filled up solid with compound and the "drawn-in" system has cast-iron pipes for conduits, then the cheaper method is probably the latter, as in this the cables are not usually so strongly armoured as in the former. After the cost the convenience of access in the "drawn-in" system strongly recommends this method, although it has several disadvantages. The conduits are always liable to infiltrations of water and gases, and if the insulation is not perfectly waterproof, a fault may easily occur. Further, wherever gas collects there is always the possibility of an explosion. The conduits are usually connected with the drain pipes so that the water may run out almost as quickly as it enters. In the solid system there are no spaces in which gas may collect, and the insulation is usually waterproof, therefore the small amount of water which may penetrate the compound around it may be ignored.

Uses of Different Insulations. The different kinds of insulations mentioned have their respective advantages and disadvantages for special classes of work. For a material to be a good insulator it should be moisture-resisting, because moisture is a conductor, and lowers the effectiveness of the insulation: it must be strong and tough, so that it can withstand the rough usage it receives in laying without splitting or tearing, and it should be flexible so that it can be easily wound on drums or bent round sharp corners underground. Further, it is desirable that it should withstand a fairly high temperature without being injured permanently, as heat is generated by the passage of the current along the conductor, and it should be practically unaffected by the acids and gases it is likely to meet when laid in the earth. In high-pressure circuits the insulation must be a very homogeneous mass, because it has to offer great resistance to disruptive discharge. When an installation is found with all or most of these properties, the best cable is that in which the cost, bulk, and weight are least. Good quality of indiarubber, properly applied, possesses almost all these qualities; therefore, from a purely technical point of view it is undoubtedly the best insulator known. Its one great disadvantage is that it is expensive.

Bitumen compound is a fairly good insulator for low-pressure work, but as it cannot withstand much heat without softening, it is unsuitable for heavy current work, where a large amount of heat is generated. Its resistance, thickness for thickness, is not quite so good as indiarubber, but it has the advantage of being cheap. Gutta-percha has a comparatively low melting point, and is therefore confined chiefly to insulation of submarine cables, and underground telephone and telegraph wires, which work only at low pressure. The advantages of gutta-percha for these insulations are that it is thoroughly waterproof and lasting. Paper insulations are suitable for either high or low pressure circuits as they will withstand a fair amount of heat without serious injury. Their disadvantages are that the paper readily absorbs moisture and therefore always requires a lead or other variety of waterproof covering, which adds to the expense. The paper itself is inexpensive.

Electric Cables *concluded*

SHIRT AND COLLAR MAKING

The Making and Dressing of all Kinds and Makes of Shirts. Drafting, Cutting and Finishing. Collar Making. Popular Styles

By W. D. F. VINCENT

FORTY or fifty years ago shirtmaking was one of the cottage industries of England. The general practice then was for the large firms who supplied the shopkeepers engaged in the drapery and outfitting trades to send round to the women of the villages and small towns of the country districts the cut-out parts in a range of sizes, paying at the rate of so much per dozen for the ordinary work of making up. Specially good needlewomen, who could work neat buttonholes and do the other parts of the work exceptionally well, found this a good means of adding to the domestic income.

The general adoption of the sewing machine, and its introduction to the factory system of working, brought about a change in this class of work. It ceased to be a home industry in the sense of home-workers being employed to supply the wholesale merchant with his requirements. Big shirt factories were established in several districts, Devonshire and Belfast being the leading centres, the latter doubtless by reason of its being the seat of the Irish linen trade. London also has become an important centre for the manufacture of linen shirts and what may be called kindred articles, such as collars, cuffs, and the now almost abandoned shirt-front or "dickie."

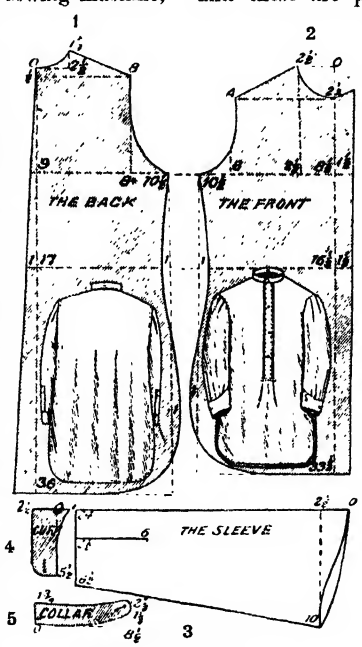
Whether, however, the goods are made at home or in the factory, the principle of production is practically the same.

Cutting Out the Material. In the factory the first thing is to cut out the material in the most economical manner. This is done by laying out a number of folds of the material to be used, and placing the various parts of the pattern, which are usually cut out first of all in tin or stout cardboard, and, after these have been marked round in pencil, cutting them out with a hand knife or band-saw in as many thicknesses as required for the different sizes.

For domestic or individual work, of course, a different plan is adopted, but it is equally important to arrange the pattern so as to use as small a quantity of material as possible.

The various parts of the shirt having been cut, the body part from calico, and front, cuffs and collar from linen, the supplementary parts have next to be attended to, such as the underlining for the cuffs, which is usually a fabric composed of a mixture of linen and cotton, and the backing for the fronts. The quality of a shirt is generally made to depend upon the fineness of the linen employed in making the front and cuffs, which is reckoned according to the number of threads to the inch, as counted through a magnifying glass specially made for the purpose.

The various parts of the different kinds of shirts will be seen by reference to the diagrams, and these are put together by the ordinary methods of sewing, the main object being to fit the body without causing discomfort at any part.



1-5. THE SAC SHIRT

The buttonholes should be very neatly worked, and a sewing machine for working buttonholes is largely used in all shirt and collar factories. This machine, by means of a kind of cross-stitching, does the sewing before the hole is cut, this being done by a chisel, or similar tool, after the shirt or collar has been finished and dressed—that is, starched and ironed.

Great care should be exercised in seeing that the buttonholes harmonise as regards position, that the hole in the back of the collar be exactly in the centre, and that those of the cuffs are properly balanced.

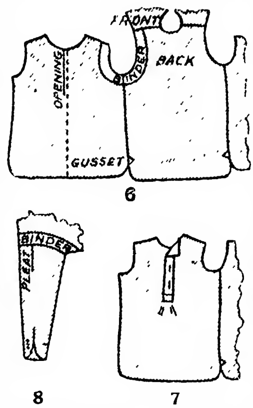
Material for Shirts. The material used for making shirts is a calico, in the trade termed longcloth, varying from 34 in. to 37 in. in width, the price ranging from 5½d. to 10d. per yard—retail—according to quality required.

The quantity of material required for two shirts with stiff fronts and wrists would be 6 yd. longcloth, 1 yd. Irish linen for frontings, and 1½ yd. of heavy interlining. The interlining might be of either linen or cotton.

The wristbands are usually made fourfold—which accounts for the extra length of interlining—to resist the greater wear on them generally. Cottons Nos. 40 to 45, 6-cord, would be suitable for bodymaking; but for fronts, wristbands and buttonholes, 60, 6-cord, would be best. For needles, Singers' ½ would be found suitable.

The material for flannel day shirts varies from 3 yd. to $3\frac{1}{2}$ yd. These are, of course, easier to make, owing to there being no stiff fronts or wristbands to be inserted. The cloth is folded in the same way as for dress shirts, but instead of cutting away a piece for the insertion of the stiff front, a piece of cloth about two inches wide is stitched down the centre, so as to form a broad plait when buttoned over. Then slope out the neck according to the size required. The neckbands of these shirts are generally made of drab or grey sateen.

The wristbands are cut so as to fit just round the wrist about $2\frac{1}{2}$ in. or 3 in. deep. Pearl buttons are used for fronts and wristbands. Owing to the greater strength required of these shirts for day work generally, the same should be made up with 6-cord cotton, 45 to 50.

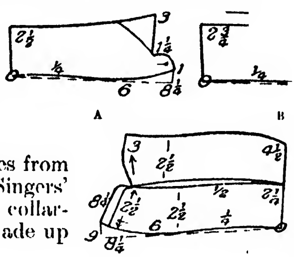


6–8. FITTING THE SHIRT TOGETHER

Linen Collars. The quantity of material required varies according to the shape of collar. The cloth used for fronting is generally Irish linen, which dresses up so much better than cotton, and imparts a higher finish to the collar when dressed, and wears longer.

The collar can be lined with either a heavy cotton or linen interlining; but the latter would be more durable, and would be found cheaper in the end.

The material for collars varies from 34 in. to 36 in. in width. Singers' 0 needles are suitable for collar-making. Collars should be made up in 6-cord, 60 to 80, cotton.



9. COLLAR DRAFTING
A. The "Wing." B. The "Stand." C. The "Double."

Diagram **9** gives reduced models of some of the most popular styles of collars, which only need to be reproduced by the ordinary inchtape to give a good model.

The variations in size can be easily made by adding to or taking from the back.

"Dressing." A new shirt should first be placed in cold water for the purpose of taking out the dress or priming of the cloth of which it is made, and afterwards taken out and washed as household linen, being thoroughly well dried in the open air before starching. While the shirt is drying lump-borax should be dissolved in the proportion of 4 oz. to 6 oz. in one pint of boiling water to half a dozen shirts. The starch (which should always be good rice starch) should then be prepared. Take 1 lb. of starch, add a little blue, which gives the shirt a whiter appearance when dressed, mix the starch in a little cold water, then add water in which the borax has been dissolved, which, however, should first be allowed to cool. The shirt being thoroughly dry, first take hold of the wristbands, and well soak and rub in the starch that has been prepared, and then deal with the front in the same way. The wristbands should next be rolled to front tightly, and the shirt allowed to remain three or four hours if possible; it could be ironed immediately if required, but in this case it would need to be first rolled in a dry cloth, or rubbed down with a dry cloth to take off the surface starch and superfluous moisture. If the starch appears a little thick when rubbing, add a little water to reduce it.

Ironing. First set, or lay out flat, the yoke of the shirt, then neck band, and afterwards the body, seam to seam.

Iron the body of shirt first, then "set" the cuffs and iron the sleeves. When this is done, prepare the front. Place a board (which should be covered with a piece of ironing flannel) between back and front of shirt, and then set for ironing. Next take an oval iron, or polisher, well heat it, and then take a piece of rag upon which a piece of beeswax has been placed, and rub the iron lightly with this—which will cause the iron to run smoothly over the starched front and wrists—but before using, wipe again with a clean duster, to remove any particle of beeswax that might be sticking to the iron. Then, with the heel of the polisher rub briskly, using the point or nose of the iron around neck band. When ironed, fold, and press with flat iron, well air, and the shirt is ready for use.

For the washing, drying, starching, etc., of collar, the same process is used as for shirts, but the quantity of starch required depends upon the number of articles to be dressed.

White shirts are made up in many varieties of fronts and cuffs. Thus the dress shirt has a front 14 in. or 15 in. deep, and about 11 in. wide, with one stud-hole in the centre about 5 in. or 6 in. down from the collar.

The ordinary, or everyday, shirt has a front ranging from 11 in. to $13\frac{1}{2}$ in. long, and 8 in. to 9 in. wide, with two or three buttonholes up the front.

Short-fronted shirts are also made for those who wear high buttoning vests, and the newest style of these are V-shaped, which gives much more comfort than the old round pattern.

Many shirts are now made up with soft fronts, or in other words without the insertion of any kind of front, and it is to this class that the flannel shirt belongs.

Cuffs are usually placed at the wrists, but many are now made with detachable cuffs. Occasionally, shirts are made up with collars attached, but this is the exception.

The fastening can either be arranged up the the front or the back, but the latter plan is preferred. A slit is made about 12 in. deep, and a facing seamed on and the band arranged accordingly.

Football shirts are made up in all kinds of patterns, according to the club selection. The illustration [19] shows the harlequin design, but this is one of scores, including many varieties of stripes, bands, stars, and other designs. They are usually finished at the neck with a turnover collar, and a patch pocket on the breast.

The night shirt is made longer and fuller than the day shirt, but generally speaking is of the same design [14]. It is finished at the neck with a turnover collar and a breast pocket. Occasionally the bottom of the back is cut ten or twelve inches longer, turned up to form a kind of pocket for the feet.

An excellent book on cutting and making all kinds of shirts is published by the John Williamson Co., Ltd., Gerrard Street, W., from whose pages we have reproduced the following system of cutting the two principal styles.

Taking the Pattern. We first proceed to describe the system, and in order to make it as simple as possible we have selected a style of shirt which is very free of complications, and will describe the cutting of this by divisions of the breast measure system for which the ordinary measures of length and width, the same as for a coat, will suffice.

THE BACK [1]. Draw line O 36 and mark off as follows: O to ½, ½ in. O to 9, one-sixth breast plus 3 in. O to 17 the natural waist length. O to 36 the full length desired plus the seams. O to 2½ one-sixth neck.

From these points square lines across at right angles.

2½ to 1¼ one-twelfth neck, and curve back neck. 1¼ to 8 the width of shoulder, as taken on customer, plus two seams. Square down from 8 to 8*. 9 to 10½ one-fourth breast plus 1½ to 2½ in. Square down from 10½, and hollow on line 17 1 in. and add on 1 in. of spring over the seat.

Mark out from 17 1 in., and draw line from O through 1.

THE FRONT [2]. Draw line O 33½. O to 2½ one-sixth neck. O to 8½ one-sixth breast plus 2½ in. O to 16½ natural waist length less ½ in., or by making the distance from 8½ to 16½ the same as 9–17 of the back. 16½ to 33½ 2 in. less than 17 to 36 of the back. Square lines from O, 2½, 8½, 16½, and 33½. O to 2½ one-sixth of the neck. 2½ to A the same as 1¼ to 8. 8½ to 8 one-fourth breast less 1in. 8½ to 10½ one-fourth breast plus 1½ in. to 2½ in. Hollow waist 1 in. Give 1 in. of spring under the hips. Add on 1½ to 2 in. for button-stand and front pleats.

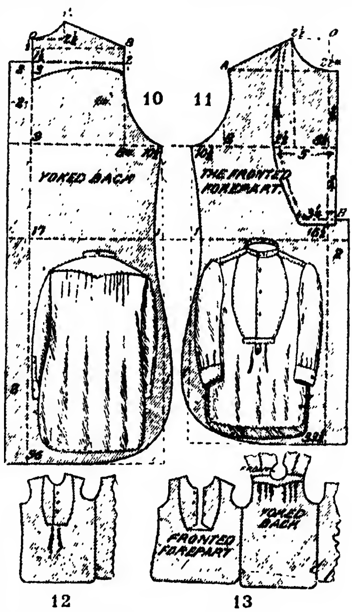
THE SLEEVE AND CUFF [3 and 4]. Draw line O 24. O to 2½, 2½ in. to 3½ in., the smaller quantity for easy-fitting sleeve. O to 24 the length of sleeve less cuff and shoulder-width, due provision being made for seams. 2½ to 10 half scye plus 1 in. to 1½ in. 24 to 6½ one-sixth breast plus ½ in. Cut as in the underpart, about 2 in. or 2½ in. from the crease.

For the cuff [4] draw lines O 2½, O 5½. O to 5½ half size of cuff desired, plus 1 in. O to 2½ depth of cuff desired plus ½ in. Add on point at 1 or shape to taste.

The cuff may be varied considerably, and this is but one style of many.

THE COLLAR [5]. Draw line O 8½. O to 8½ half neck plus 1 in. 8½ to 1½, 1½ in. Draft collar 1¾ deep at back and 1 in. deep at front.

The Finished Article. In the accompanying diagrams we give a few suggestions on making-up. Diagram 6 shows the back joined to the front at the shoulders and the side; about 2 in. from the bottom of the side seam a gusset is put. The opening is cut down the front about ¾ in. to the right of the centre and about 13 in. deep. This is then turned in, and forms the button-stand, whilst the other side is turned in to form a pleat, and the underpart turned over to meet it, the holes being worked in this as shown in 7.



10-13. YOKED AND FRONTED SHIRT

In 8 we show the sleeve made up; the fulness at the top may either be put in the form of pleats or gathers, which also applies to the cuff; the slit of the sleeve should be faced so as to take buttons if necessary. Binders are often put on round the armhole in order to strengthen it at that part. These are shown in 6 and 8.

Yoked and Fronted Shirts. The vast majority of shirts are now made up with yokes and inserted front. This plan is now adopted not only for white and coloured linen shirts, but also for flannels, so that this is by far the most popular style of shirt at the present time. These two features do not necessarily go together; the yoked back may be used with the plain forepart [2], or the fronted forepart may be used with the sac back [1].

THE YOKE BACK [10]. Draw line O 36. O to ½, ½ in. O to 3, 3 in. more or less to taste. O to 9 one-sixth breast plus 3 in. O to 17 natural waist length. O to 36 full length of back plus two seams. Square lines at right angles to these points. O to 2½ one-sixth neck. 2½ to 1¼ one-twelfth neck, and curve back neck. 1¼ to 8 the width of shoulder plus two seams (½ in.). Square down from 8 to 8*. 9 to 10½ one-fourth breast plus 1½ in. to 2½ in. Square down from 10½. Hollow inside this line 1 in. at waist, and add 1 in. of spring over the seat. Shape bottom of yoke to taste. In the diagram it is pointed in the centre, which is 3 in. down

from O. The depth at the scye is 2 in. Let back overlap this at the shallowest part at least ½ in., as shown by dot and dash line.

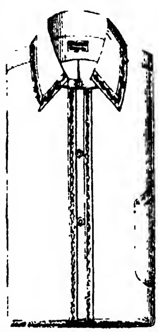
THE FOREPART [11]. Draw line O 33½. O to 2½ * one-sixth neck. O to 8½ one-sixth breast plus 2½ in. 8½ to 16½ the same as the back from 9 to 17. 8½ to 33½ about 2 in. less than 9 to 36 of the back. 8½ to 2½, and O to 2½, each one-sixth of the neck.

Square across from 2½* to A, and make 2½ to A the same width as 1¼ to 8 of the back.

8½ to 8 one-fourth breast less 1 in. 8½ to 10½ one-fourth breast plus 1½ in. to 2½ in. Square down from 10½.

Hollow side seam at waist 1 in., and give about 1 in. of spring over the hips.

THE FRONT. The shape of the front varies considerably, but the more general size is that indicated on this diagram.

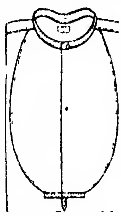


14. NIGHT SHIRT

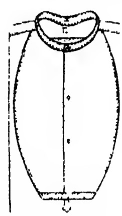
The depth extends to within 1 in. or 1½ in. of waist line, 16½.

The width of the front at the bottom is 3¼ in., including the ¾ in. buttonstand added beyond the centre line.

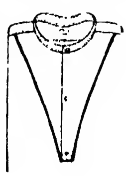
The width across the widest part of the breast just below the depth of scye line is 5 in., including the ¾ in. buttonstand. From this point it is continued up to the shoulder seam, where it is made 1 in. wide.



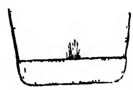
15. DRESS SHIRT



16. MORNING SHIRT



17. FRONTED SHIRT



18. DETACHABLE CUFFS

To provide for seams where the front is joined at the breast, allow ¾ in. at both side and bottom.

From B downwards allow 2 in. for pleat at bottom of the front.

The sleeve, cuff, and collar are as described on 3, 4, and 5, though in the illustration we show a plain round cuff; that, however, is a variation easily introduced.

19. FOOTBALL SHIRT

Important Details. The yoke is intended to be double.

The extra width of the back is either gathered or pleated in to the yoke just above the blades on either side of the point, leaving about 1½ in. plain on either side of the point. This is shown in **13**, as well as the joining of the forepart to the yoke.

In **13** we also illustrate the front sewn to the forepart down the sides, from which it will be seen there is extra width on the forepart below to be gathered or pleated in. This is generally done by a box-pleat, and the bottom of front is either finished with a strap, or the front is left long enough to overlap the necessary amount.

On the figure in **11** we illustrate the strapping method, and in **12** the plain method.

These fronts are either made double, or of more thicknesses.

When working-men's shirts are made up from Oxford shirting in this way, the lining of the front is of unbleached calico.

When flannel shirts are made up in this way, the inner front may either be of the same flannel or a thinner one.

The number of holes put in the fronts is usually three, though for dress shirts this number is sometimes reduced to one.

For white linen or cambric shirts the fronts are made up with four thicknesses, to take the starch, and in this case the cuffs follow suit.

A tab is often put on the bottom of the front to fasten it to the top button of the trousers.

All the seams are turned in and stitched or felled, and are never left raw. This necessitates the provision of rather wider seams than the usual ¼ in., so that they ought not to be less than ⅜ in. or ½ in. The bottom side seams are left open about 3 in. or 4 in. up, and the top of the slit finished with a gusset.

The other diagrams on this page not already referred to [15–18] serve to illustrate the various styles when made up, and are explained in the descriptions given underneath.

COMPANY FORMATION

The Company Promoter and His Duties. Articles of Association. Directors. Working a Limited Company

By D. N. DUNLOP

THE fundamental principle underlying all joint-stock enterprise is financial co-operation, which legislation endeavours to place on a sound basis of equity. The very freedom of the system of British Company Law, as set forth in the Act of 1862, constitutes its gravest danger. Abuse of this freedom by unscrupulous promoters and directors led to further measures for the protection of the public in the shape of the amended Companies Act of 1900, without seriously curtailing the freedom. This Act provides that all the information likely to influence would-be investors no less than the absolutely essential facts, should be registered and made public, thus insuring that companies should not be launched without due guarantee of soundness, or without giving the investing public a chance of judging of the merits of the enterprise. The Act secures, in addition, a more intimate control on the part of shareholders, and protects creditors of the company by enforcing a public registry of all mortgages and charges created by the company.

British company law is now, in its amended form, as perfect as criticism and experience can make it, while refraining from exercising a cramping or stifling influence on commercial and industrial enterprise. Against the individual losses and mischief imputed to joint-stock companies in the past must be set the immense benefits which the stimulus of the co-operative principle, combined with limited liability, has conferred upon British trade. Joint-stock companies are divided into three classes:

(A) Companies with unlimited liability;

(B) Companies whose liability is limited by shares;

(C) Companies whose liability is limited by guarantee.

Class A is now practically extinct. B is the normal type and by far the most important.

The Promoter. What are the legal position, the responsibilities, and the risks of the business man who becomes a company promoter? The most frequent cause of disaster to the amateur promoter is ignorance or misapprehension of his fiduciary relation to the company he promotes, as understood in the doctrine of equity. The duties, responsibilities, and obligations of a promoter which constitute his fiduciary relation to the company are various and great. The promoter, or promoters, of a company have in their hands, as Lord Cairns puts it, the creation and moulding of a company. They have the power of defining how, when, and in what shape and under what supervision it shall come into being and begin operations as a trading company. The promoter prepares and settles the memorandum and articles of association of the company, furnishes it with directors and fixes the minimum subscription on which the directors may go to allotment. In one word, his will controls the future destiny of the unborn corporation. It stands to reason that, under these circumstances, equity demands that the promoter should not abuse his trust by taking advantage of his own power and the company's defencelessness to despoil it or involve it in difficulties.

The Stumbling Block. The practical meaning of the warning here conveyed is briefly this. It is assumed, as a matter of course, that a promoter does not undertake to promote a company for nothing. He may have some property he wishes to dispose of to the company when formed, such as a business, a mine, a concession, a patent, etc., or he may be induced to give his services for a consideration in cash or shares. The point at issue is this: he may make any condition he thinks fit, arrange for the disposal of his own property, or of property in which he is interested, on terms advantageous to himself, but he is compelled to make full disclosure of his interest and position in regard to one or other of these profits. The penalty in case of failure thus to disclose his interest is that he is not by law allowed to retain such profit. If he dispose of a business to the company, the accounts must be audited and the value of the undertaking strictly estimated on an equitable basis. If he sells a property such as a mine, *he is bound to disclose the profit he is making by the transaction*, for he stands in the position of trustee to the company he is promoting. The company must enter into a contract with him with its eyes open.

The position of the promoter is, therefore, that the company has in equity the right to all profit or remuneration obtained by the promoter as its trustee unless it has waived that right after being put in full possession of all the facts—that is, of the nature and amount of the interest. The Act further demands [Sec. 10 (1)] that any such moneys and interest shall be specified in the prospectus, so that the company—that is, the shareholders—may duly take this into consideration before investing their money in the concern. It is the duty of the directors to see that this disclosure is duly made in the prospectus, for once they are appointed, the liability is shared by them. A vendor to any company about to be formed should, therefore, avoid any share in the promotion of the company, unless he be prepared to take upon himself the obligations of a promoter and to make full disclosure of his interest.

The Duties of a Promoter. The duties of a promoter, when forming a company, are as follow:

(1) To prepare a draft of the preliminary agreement in case of property or enterprise to be acquired by the company.

(2) To prepare the memorandum and articles of association of the company and to get six other persons of full age to subscribe them (they need not subscribe more than one share each).

(3) To pay duty on the company's capital and the registration fees.

(4) To select and appoint a board of directors to act.

(5) To file their consent to act with the registrar.

(6) To present the memorandum and articles for registration, together with a statutory declaration.

(7) To prepare the prospectus according to statute (Sec. 10 (1)], being careful to include the thirteen particulars of disclosure required by law.

(8) To have the prospectus signed by all mentioned therein as directors.

(9) To file the prospectus with the registrar.

(10) To advertise the prospectus.

The Directors' Preparations for Business. The company is now promoted and the shares have been publicly offered for subscription; as soon as the minimum subscription, specified in the prospectus, or failing this, the whole of the nominal capital, has been subscribed, the directors take the following steps before the company is ready to begin business as a trading company:

(1) Proceed to the allotment of shares.

(2) File a return of the allotment with the registrar.

(3) File a statutory declaration for the commencement of business according to Section 6 of the Act and obtain from the registrar a certificate entitling the company to begin business.

Management of the New Company. Further immediate steps in the management of the newly registered company include the following:

(1) Prepare preliminary report for presentation and discussion at the first statutory meeting of shareholders (Sec. 12), which must be held not more than three months after the date of the certificate authorising the company to begin business.

(2) File this report and obtain a certificate for it from the registrar.

(3) Circulate the report, sending a copy to each shareholder at his address in the register, *seven clear days* before the day appointed for the statutory meeting.

(4) Hold the statutory meeting (Sec. 12).

(5) Register mortgages and charges and endorse on every debenture or debenture stock a copy of the registrar's certificate of registration (Secs. 14 to 18).

(6) Preserve and file copies of instruments of mortgage or charge for inspection at the registered office of the company.

(7) Keep a list of directors at the registered office of the company and send returns to the registrar.

(8) Make out an annual summary and list of members.

The above is the correct statutory order of procedure in the formation of a company. We shall now examine some of the essential points a little more closely.

The Memorandum and Articles of Association. The memorandum of association is the basis or charter of the company's constitution, and as such is a public document registered with the articles of association at Somerset House. Five important points are required by law to be set out in the memorandum, as follows:

(1) The name of the proposed company, with the addition of the word *Limited* as the last word in such name.

(2) The part of the United Kingdom, whether England, Scotland, or Ireland, in which the registered office of the company is to be situated.

(3) The objects for which the proposed company is to be established.

(4) A declaration that the liability of the members is limited.

(5) The amount of capital with which the company propose to be registered, divided into shares of a certain fixed amount.

The Objects Clause. No. 3 is the most important of the clauses. Once the objects are specified, the company is bound down to these and cannot undertake anything beyond these. By the definition of these objects, as stated in the memorandum, the sphere of the company's activities is strictly limited. The State, having incorporated the company for a special purpose, in respect of which shareholders invest their money, will not authorise the money being applied to any other enterprise, held to be ultra vires or in excess of their statutory powers, even by full consent of the shareholders. Hence, certain powers, such as borrowing powers, power to accept bills of exchange and other negotiable instruments, power to sell and dispose of the company's undertaking without a winding-up, or to promote another company, power to pay preliminary expenses and the amount of the minimum subscription on which the directors will proceed to allotment, should all be inserted in the memorandum. In addition, it should be distinctly stated of what kind of shares the capital is to consist, whether there be preference shares, and if so, what privilege and rights they carry, and whether the preferential dividend be cumulative or not.

The memorandum and articles of association must be duly signed by seven persons of full age and not standing under any legal disability. Each signature must be duly witnessed. The memorandum need not necessarily be printed, but the articles are required to be printed; both must be stamped with a 10s. deed stamp and with the fee stamp, and must be registered by the Registrar of Joint Stock Companies at Somerset House.

The Board of Directors. There are several important points in connection with the position of a director in a joint-stock company which should not be lost sight of.

The company, being a legal abstraction of a co-operative aggregate, cannot do anything of itself or act except through agents, known variously as directors, managers, council or board. The law regards them all as directors, if they are the accredited representatives or agents of the company. The directors are chosen by the promoter, who is generally anxious to secure an attractive board, which will form a guarantee and induce the public to subscribe. Great abuses have arisen out of this inducement held out to the public: names of weight have been prematurely advertised as directors, sometimes on the faith of a half promise, sometimes as a decoy which has proved only too successful, the public discovering too late that the very man whose name formed a guarantee of success had refused to act as director.

The new Act of 1900 (Sec. 2) has effectually prevented this abuse by requiring that the consent in writing to act as director must be filed before the articles nominating him as director can be registered or the prospectus issued.

The director is further required to subscribe the memorandum of association for his qualification shares, or to sign and file with the registrar a contract in writing to take from the company and pay for his qualification shares (if any). The first of these courses is to be recommended, as the second presents serious difficulties owing to the fact that a contract cannot be made with a company which has no legal existence; and if it be made with the promoters, the company, not being a party to the

contract, would have no locus standi to enforce it. The director must take his qualification shares *from the company* and within two months of his appointment, or else vacate the office.

If a director be not legally appointed in accordance with these requirements of the Act and yet exercises the functions of a director, he is liable to a penalty of £5 a day.

A director is criminally liable for any fraud, misstatement, false statement, failure to disclose or to comply with the statutory conditions of which he was cognisant, or of which it was his duty to be cognisant, but he is not liable for the frauds of his co-directors, if he be himself deceived by them; or for mere errors of judgment. Directors are, in short, expected to fulfil their duties as agents faithfully, honestly, and diligently. When guilty of a breach of trust, the company has the remedy of bringing an action against the director for misfeasance; if the company is being wound up, a misfeasance summons may be taken out by the official receiver or by a creditor, compelling the director to repay misapplied moneys or to make compensation for loss.

Going to Allotment. In the past, winding-up orders were frequently due to the undue precipitation of the directors in proceeding to allotment before a sufficient subscription had been raised. By Section 4 of the Act of 1900, legislation seeks to obviate this danger, by requiring that allotment shall be made only when the amount fixed by the memorandum or articles of association as the minimum subscription has been subscribed, or, if no amount has been fixed, then the whole amount of the share capital. Both these amounts are to be reckoned exclusively of any amount payable otherwise than in cash. Other sub-sections fix the amount of the shares payable on application at not less than 5 per cent. of the nominal amount of the share. The time limit allowed the company for raising the minimum subscription is 40 days after the issue of the prospectus, on the expiration of which, if the directors may not proceed to allotment, they must forthwith repay all money received from applicants for shares. Repayment *without interest* must take place within 48 days after the issue of the prospectus; after that period, repayment is burdened with interest at 5 per cent.

Although directors may not proceed to allotment before the minimum subscription has been raised, they may give a provisional acceptance of a subscriber's application, subject to the statutory conditions as to allotment, provided they notify him to that effect.

Beginning Business. A point of the utmost importance to persons dealing with a company in the early stages of its existence is the question of contracts. No contracts entered into with a company before the certificate entitling it to begin business has been granted is binding on the company; it is only provisional—that is, contingent on the grant of the certificate. But on the day the certificate is granted, *the contract becomes* binding, says the Act [4 (Sec. 3)]. The contracting party cannot, however, withdraw from his agreement with the company, pending fulfilment of this condition, unless the prospectus contain any false or fraudulent statement material to the contract, in which case he is entitled to rescind his agreement.

Mortgages and Charges to be Registered. There are four classes of mortgages and charges which are required by the Act to be registered [Sec. 14 (1)]:

(*a*) A mortgage or charge for the purpose of securing any issue of debentures (including debenture stock);

(*b*) A mortgage or charge on uncalled capital of the company;

(*c*) A mortgage or charge created or evidenced by an instrument which, if executed by an individual, would require registration as a bill of sale;

(*d*) A floating charge on the undertaking or property of the company.

All these classes of mortgages and charges must be registered by the Registrar of Joint Stock Companies at Somerset House. The points to be entered on the register are:

(1) The date of the creation of the mortgage or charge.

(2) The amount secured thereby.

(3) Brief particulars of the property mortgaged or charged.

(4) The names of the mortgagees or persons entitled to the charge.

In the case of debentures it is sufficient to register ·

(1) The total amount secured by the whole series.

(2) The date of the resolutions creating the series and of the covering deed (if any) by which the security is created or defined.

(3) A general description of the property charged.

(4) The names of the trustees (if any) for the debenture-holders.

These provisions form the investor's safeguard, for, as mentioned above, every debenture stock must be indorsed with a copy of the registrar's certificate of mortgages and charges. But as the Act does not cover any but these four classes of charges, it will be seen that there are risks outside this certificate which must be either inquired into or covered by insurance.

Inspection of Registers. The register at Somerset House is open to inspection by *any person* on payment of a fee not exceeding 1s. The company's own register is, on the other hand, accessible only to members or creditors.

The company is compelled to keep on record a copy of every instrument creating the mortgages and charges which come within the section of the Act, and to allow any member or creditor to inspect the same on payment of a fee not exceeding 1s. It is well to note that the right to inspect also covers the right to copy, and that a shareholder can depute his right to inspect to his solicitor.

Every shareholder has a right to transfer his shares, subject to the regulations of the company, who may require that all transfers receive the approval of the board of directors before registration. This regulation is often included in the memorandum or articles in order to protect the company against insolvent or undesirable shareholders. The directors' right to veto, however, applies only to cases in which the objection is to the transferee and not to the purpose for which the transfer is effected.

LIFE AFLOAT

Climbing the Ladder of Promotion on Board Ship. The Mercantile Marine. Examinations for Ship Officers. The Routine of the Ship

Continued from page 6665

By J. P. LORD

THERE is one point about the merchant service which is especially attractive to the youth who desires to go to sea—namely, that birth and influence are not necessary to attain command, fitness being the only requisite.

Staff of a Steamship. The staff of a large steam vessel is divided into three main sections, at the head of which stands the captain. First, there is the executive, or deck staff, consisting of the captain himself, and at least two mates, but usually three or more, as officers. Petty officers are the boatswain and his mate, the carpenter, quartermasters, the sailmaker, and gunner. Then comes the crew, divided into A.B.'s, or able seamen, ordinary seamen, and boys. Next comes the purser's staff, consisting of purser, clerks as officers, stewards as petty officers, and assistant stewards, cooks, cabin stewards, and cabin boys, as crew. Lastly, there is the engine-room staff, commanded by the chief engineer, with second, third, and fourth, and possibly more, engineers as his assistants, especially where a refrigerating plant is installed. Greasers, donkeyman, firemen, and trimmers, form the complement of the crew.

The first division is the most important, and as it is the only one in which command can be obtained, or in which the highest posts are open to the penniless youth with no influence of any kind, we shall consider it first.

We shall premise that the would-be sailor is between fourteen and sixteen years of age. He wishes one day to be a captain, and wants to know how to attain his ambition. There are two recognised methods of becoming an officer in the mercantile marine. The first is to work one's way up from the bottom; the second, or more aristocratic method, is by apprenticeship. Working one's way up is known as "coming through the hawse holes"; but, provided that the officer who has attained rank in this fashion is skilful, smart, and gentlemanly, he will not find that stand in his way. Some of our best captains have been "before the mast," as being a common sailor is called. We shall take this method first, detailing the duties of the various members of the crew and petty officers.

Joining a Ship. The youngster who desires to join a ship should apply to the shipping master at any of our large ports from which sailing ships set out, for though a modified qualification can be obtained by joining a steamer, still, that qualification is of little use in later life. A ship having been found for the boy, he will have to sign on the articles in that capacity, appearing at the shipping office for that purpose. His pay will be merely nominal, ranging from 6d. a month to possible 4s. On board, he will have to make himself generally useful, being at the beck and call of everyone in his department. He will learn to go aloft, to splice and make knots, and to clean brass-work. From his elders he will pick up a considerable amount of knowledge, and after he has been a few voyages, or possibly only one, if he is about seventeen, he will be given a discharge as an ordinary seaman. At the end of each voyage, when the crews are paid off at the shipping office, each member receives a discharge paper, stating the length of the voyage, the conduct of the individual, and his capacity. These he must preserve, as he must show them when he seeks another ship.

Ordinary Seaman. As an ordinary seaman, the young sailor will be expected to be capable of taking his part in the working of the ship, but he will not be expected to steer, nor will he generally be entrusted with repairing the more important portions of the rigging. He will have to take his turn at the "look-out" during his watch. Here we may say that the crew of a ship is divided into two watches, the "starboard" and "port," and each is on duty for four hours at a time, beginning at 4 a.m., except during the dog watches, which are only of two hours'duration—namely, from 4 p.m. to 6 p.m., and 6 p.m. to 8 p.m. The object of the dog watches is to ensure a change for the men, those who have two night watches one day having only one the next. The ordinary seaman has to help to stow cargo, under the direction of the mate, unless he is occupied in hauling on the ropes of the derricks, a task at which he is generally employed. If he shows himself smart, he may be allowed to take a hand at the wheel in fair weather, or may be put to assist an A.B. in heavy weather, and thus he learns how to steer. When he can do this, and has shown himself smart aloft, he will get his discharge as A.B., or *able-bodied seaman.*

The "A.B." To get thus far usually takes a youngster four years, and he does not then remain in the forecastle, where the men are berthed. If he is desirous of being an officer, the Board of Trade requires only that an applicant for examination for second mate shall be able to show discharges for four full years at sea on an ocean-going vessel. If, however, he has not put in his full time the A.B. must ship in that capacity, when his pay will be between £2 and £3 a month. As A.B. the sailor is expected to be accomplished in all the ordinary knots and splices, to be able to steer accurately, to heave the log (under supervision), and to know the marking of the hand lead-line, and to be able to give the correct depth of water when using it, to manage a small boat, and to do any work aloft or on deck which may be required of him. The A.B.'s are the seniors in the forecastle, and a certain proportion of them are distributed in each watch.

Petty Officers. The carpenter and sailmaker are artisans who have learnt their trade ashore, as well as having had practical training at sea, when, as A.B.'s, or even ordinary seamen, they have been attached as mates to carpenters and sailmakers. They look after the up-keep of the fabric of the ship, and the repairing and making of the sails. Besides this, the carpenter takes soundings of the wells in the ship at regular intervals, and reports to the officer of the watch how much water there is in the bottom of the vessel, for very few ships are absolutely dry. In times of emergency, he has to be able to perform the ordinary duties of a sailor, and go aloft to make or take in sail.

The boatswain and his mate act as sergeants over the two watches, directing work to be done rather than doing it themselves. However, when an officer

is supervising, they have to take their share of the labour. They are always experienced men, and when really good, are of more real service to the captain than some of his junior officers.

Quartermasters and Gunners. Quartermasters and gunners, when native crews are carried, are usually to be found only on board large steamers. The former are in charge of the wheel, two being attached to each watch, and taking turns at the helm. They act as general messengers for the officer of the watch, see that the lights are properly burning, and that the look-out is on the alert. They strike the bell every half hour, assist in heaving the log, or take readings from the patent log, make signals with flags, and attend to the rockets and fire signals. The gunners are practically only cargo officers. They take charge of the hatches, seeing that the cargo is put in properly, and generally assist the officers on duty. They look after the ship's armoury, and keep all the bright work clean. When there are many boats attached to the steamer, some of them are in charge of the gunners. When the cargo is in the hatches, the gunners have to send to the clerks and purser accurate lists of what is in the hatches to which they have been appointed. They make themselves useful, standing by and passing the word, and so forth, and have their proper stations at boat and fire drill. On boats manned by natives, the gunners are selected for their knowledge of the language and are often themselves half-castes. While speaking of lascar crews, we may mention that the quartermasters, where native, are called *seacunnies ;* the boatswain is the *serang*; his mates, the *burra* and *chota tindals ;* and the carpenter is the *mistri.*

The cook and cook's mate, with the steward, are the only members of the purser's staff carried on sailing ships which do not carry passengers. The steward is usually the captain's private servant, who looks after the stores and their issue. He is rarely a sailor. The cook and cook's mate are both supposed to be sailors, and are liable on board smaller vessels to be called on to go aloft and assist in the working of the ship at any time. The Board of Trade accepts service as a ship's cook as proof of practical sea training, and four years' service as such entitles a man to go up for examination as an officer, though, naturally, this privilege is seldom exercised.

Becoming an Officer. Having put in his time at sea, and got his rating of able seaman, the young man is qualified to go up for his examination as second mate, the first step to responsibility. But to do so, he will require to have studied hard during his spare time at sea. This is essential as far as seamanship is concerned, but for navigation he need not be so particular, for much of the work can be learned ashore in one of the many excellent nautical schools, a short sojourn at one of which is now becoming more necessary. Before dealing, however, with the examinations requisite to enable the youngster to assume the blue and gold of an officer we must describe the more general method of becoming an officer—namely, by apprenticeship. Many of the large firms of shipowners accept apprentices on their sailing ships, receiving premiums which vary from £20 to £150. The apprentices are either berthed aft, close to the captain's cabin, or have a house to themselves on the quarterdeck. They have to do the ordinary work of sailors, under the supervision of the officers and with the assistance of several qualified sailors. To them is generally entrusted the management of the sail on the mizzen mast. They are expected to watch the officers taking sights and calculating the ship's position, and after a time are also permitted to take sights for themselves with a sextant. They take their meals by themselves and not with the men or officers, unless on special occasions the captain extends hospitality to them. In good ships they are very carefully watched, and the difficulty of their work is graduated, so that before their time is up they are usually good practical sailors. Knotting and splicing is taught to them by the A.B.'s or boatswain, and the captain or first mate frequently teaches them the elements of navigation. At the end of their apprenticeship they are entitled to go up for the Board of Trade examination. In some ships the smartest apprentice is often given honorary rank as third officer, and thus he learns how to give orders as well as to obey. To shorten the apprenticeship, those who can afford it can be sent to the Worcester or the Conway, two excellent training ships for the mercantile marine, where, prior to going to sea, the boy is taught a certain amount of navigation and seamanship, and enters his new profession with a fair theoretical and practical knowledge of his calling. Two years on either of these vessels counts as one year at sea for purposes of qualification.

First Examination. Whether the candidate has acquired his knowledge before the mast or has been an apprentice he must now pass the examination for second mate, the lowest qualification recognised by the Board of Trade. The examination is held at various large ports throughout the world, but "tickets," as certificates are called, obtained from London are held in the highest esteem by sailors, though all are equally good from the shipowner's point of view. Tickets are of three classes: *Full* tickets, those permitting the aspirant to command any class of vessel (for these, at least a year of the apprenticeship must have been passed in a square-rigged vessel); *fore and aft* tickets, which permit the holder to hold office in the vessels of the schooner type or in steamers; and *steam* tickets, which grant permission to be an officer only on steamships. The last two are not to be recommended. Every sailor should strive to obtain the full ticket. So many fully qualified men are to be obtained that few shipowners care to employ men with lower tickets, always with the exception of the small coasting trade.

The subjects of the examination, which is fairly exacting, are seamanship, embracing the management of all sails and rigging; the standing and running rigging of ships: the bending, unbending, setting, taking in and furling of sails; the management of a ship under canvas, especially in sudden squalls; the rule of the road at sea, and what course to steer to avoid a collision; the lights carried by ships and steamers of every description, and their fog and sound signals; signals of distress, for pilot, and the penalties for misusing them; marking and use of lead line; sending masts and yards up or down; management of boats in rough weather; dunnaging and stowing cargo. Failure in this part of the examination necessitates going to sea again for six months.

In navigation the second mate must show an efficient knowledge of principles, understand all terms, and be able to find the ship's position by ordinary methods, those of Sumner and latitude by altitude of Polar Star excepted. He must know how to estimate the error of a compass or a sextant, and correct the same as far as possible, or to make tables of the errors for future calculation.

He must know how to enter in the log the "Day's Work," and how to use the same for navigation, and find position by dead reckoning as well as by observation. Parallel sailing and Mercator's sailing must be learnt. Amplitude, tides, azimuths, chronometer, longitude by azimuth and chronometer combined, and the use of true and magnetic charts all find a place in the examination, which, as will be seen, is fairly comprehensive. The simple mathematics is confined to the correct use of logarithms, and a small acquaintance with trigonometry, though not a subject of examination, is almost essential. In addition to this examination the candidate will have to pass the Board of Trade sight test, to ensure that he is not colour blind.

Second Mate's Duties. The newly fledged second mate will now have his choice of entering the service of some steamship company or of remaining in a sailing ship. If he goes in the latter he will probably be rated as second mate, and will have to share the watches with the mate and captain. He will be in charge of the deck at fixed times, and when he goes on duty he will receive from his predecessor the orders which have been given by the captain, and will also see that they are written down in the log before the officer relieved goes off duty. He will have to see the holds properly loaded with cargo. He will have a portion of the rigging under his charge and will have to overhaul it at intervals and report thereon. At stated times he will have to work out the ship's position and generally assist in the navigation of the vessel. For the first time he will be in real authority.

Duties of Third and Fourth Mates. On a steamer, however, the newly-made mate will not have much chance of obtaining a post as second mate right away, except on small tramp vessels. He will probably have to sail for some considerable time as third officer, and even as fourth or fifth. The fourth and lower officers in large vessels are not usually in charge of a watch, but are employed in looking after cargo, baggage, mails, passengers, the fabric of the ship and so forth: they are attached to senior officers and work under their directions. The third officer—for on steamers the word *mate* is forgotten—is, however, in charge of a watch, the captain keeping no watch. The third officer's watch is generally from 8 till 12, morning and evening, during which time he has in all things to behave as if in command of the vessel, save when running into danger, or if there be a sudden change of the weather, when he sends a report to the captain. He must never leave the bridge during his watch. He will also be in charge of a hatch, and, like all hatch officers, will have to see the cargo properly stowed in the holds, subsequently writing up a list of what is in his hold, and its destination, which he will forward to the purser or clerk, together with his gangway book, in which a fair copy of this is entered. Twice a day he will have to take sights and determine the ship's position, sending in his report to the captain. All officers above the third have also to do this. He will relieve the bridge for meals, unless a fourth officer is carried, getting his own meals later. He will have to take the readings of the patent log, or send a quartermaster to do so, at intervals during his watch, and enter the same in the log book. Everything that happens during his watch will also have to be written in the log. In his relations with passengers he must not be too familiar, or he will probably be dismissed when his ship returns, the companies rightly holding that their responsible officers should not form too strong friendships with passengers lest the safety of the ship suffer. At the same time he must, when required, take a part in the festivities of the ship and generally be agreeable and courteous.

Second Mate on Steamers. After serving a time as third, the young officer may be promoted to second officer on his steamer, when he will find that his responsibilities are increased. In large vessels the second officer is usually looked upon as the navigating officer, and the captain relies a good deal upon his subordinate's calculations. Indeed, the early morning sights are very frequently entrusted solely to the second officer, much to that worthy's disgust, for as his watches are those between 12 and 4 it is a little hard on him to have to be on deck shortly after eight again, when he has had only a very short sleep. However, the increased dignity and increased pay compensate him to a great extent. In many mail steamers the second officer is in charge of the mails and is responsible for them. He has to see the bags on board, see them stowed in the mail-room, and keep the key himself. On other vessels he keeps the key of the baggage-room, and superintends the periodical baggage days. Besides this he has his hatch to look after, though custom generally gives him the hatch which is least difficult to work.

First Mate. The next examination which the officer has to take is that for first mate, or simply mate. He has to take the same subjects as the second mate, but is expected to show a further knowledge of seamanship. He must know what to do in the event of his vessel being disabled, and be thoroughly capable of executing temporary repairs of all sorts, and of rigging jury masts. He must know how to shift large spars, and manage heavy weights, even in a sea way. He must understand how to load a ship so as not to strain her, how to ventilate his holds and how to stow explosives. In the event of wreck he must be able to make the best provision for the saving of life. He must be able to dock and undock his vessel and must have a practical acquaintance with the forms to be observed in the event of his having to take a ship into port after an accident. In other words, he must show himself perfectly capable of taking entire charge of the vessel in the event of the death or disablement of the master.

Duties of a Mate. His actual duties at sea depend a good deal on the class of vessel. On sailing ships he is responsible to the captain for the proper maintenance of the spars and rigging, and for the general upkeep of the ship's fabric. On liners and steamships he is in charge of the deck, sees to the painting and repairing of the ship, indents for stores and has them issued under his supervision for keeping the vessel spick and span. He is expected to take charge of a table in the saloon at meals and to make himself agreeable to the passengers. He it is who instructs the crew in boat and fire musters, and with the assistance of the purser apportions the passengers to the various boats. He is the captain's right-hand man, and, as a rule, orders from the commander pass through the *chief officer*, as the first mate is generally called.

Examination for Master. After serving with a chief mate's certificate for twelve months at sea, even though employed only as a second mate, the officer is entitled to present himself for the master's examination. This embraces all the subjects which he had to take for his mate's ticket, but the examination is much harder. If he wishes to graduate in the Honour school, the

candidate can offer himself for the extra master's certificate, which is the most searching examination under the Board of Trade.

As captain, or master of a ship the sailor will have obtained the height of his ambition, but he will have to pay heavily for it in responsibility, for the commander is held to be responsible for everything that takes place on board his vessel unless he can prove clearly that he was in no way implicated. He is absolute king on board his ship and his word is law, but he will find that great tact is required if he is to rule his kingdom without friction, and at the same time with the necessary firmness. Sailors have small respect for a weak captain.

Where the captain has no clerk or purser to assist him he will have to prepare the papers and documents which will be described under the category of the purser's duties. He is also expected to have some acquaintance with marine engines, if he be in charge of a steamer.

In his relations with the owners of the vessel the captain will have to exercise great judgment. If he is too servile he will not be respected, and his life will be a burden to him. On the other hand he must remember that the owners are his employers, and unless he has very good cause to do so he should not thwart their wishes. But, above everything, he must remember that his first duty is to his ship and to the lives and cargo entrusted to him, and the owners must take a second place when the two interests clash.

The Purser's Department. Under the purser in large vessels is an army of stewards, clerks, cooks, and cabin servants, for all of whom he is answerable to the captain. Promotion in this department is not so sure as in the executive staff, influence having a good deal to do with appointments to the higher posts.

The purser himself is always a man of education, and in some of the larger vessels may be a member of one of the universities. He is the representative of the owners on board, and his duties are very varied. First and foremost he is in charge of all the ship's papers and either makes them out himself, or sees that they are properly prepared by his assistant or his clerk. Where there is no purser the captain sees to them.

First comes the *official log*, in which is entered records of all births, deaths, marriages, convictions of crew, punishments, fines, forfeitures, illnesses of crew, character and conduct of each member of it, collisions and accidents to the vessel, change of masters and so forth. The draught of water when the ship proceeds to sea must always be recorded in the official log. Penalty for not obeying these rules varies from £5 to £30, the latter being the punishment for making an entry of an event which occurred on a voyage after the ship has entered port and been moored for more than a day. All entries must be signed by the captain and the chief officer, or some other member of the crew.

Ship Articles. The articles contain a list of every member of the crew and also the conditions of their service and their wages, etc. They are made out at the shipping office, but on the voyage the captain can add to the number, and then must make an entry, and show it to the nearest consul when he gets to port.

The *ship's register* must be on board, but the purser does not generally keep that for it has to be posted up on passenger ships in a place where everyone can see it. Before sailing for foreign ports a *bill of health* must be obtained from the [illegible] port of departure, and this must be endorsed by the consul of the port of destination.

A number of manifests will have to be prepared for the various ports to which the ship is bound. Sometimes these are provided from the shore office, but very frequently the purser and his clerks have to prepare them. They are lists showing the particulars of the vessel herself, and a complete list of all the cargo contained in the holds, with marks, numbers, and consignees and shippers. One manifest, giving the entire contents of the ship is known as the *general manifest*, and from this a series of particular manifests have to be prepared for each port to show what cargo is to be discharged there. Copies of the particular manifest, with at least one of the general manifest, all signed by the captain, have to be delivered to the customs authorities at the various ports. In many ports lists of the ship's effects and stores have to be delivered and these are made out by the purser.

Bills of lading, which are receipts for the goods taken on board, are signed by the captain or the purser. They must correspond with the total of cargo by the officers' gangway books in which the officers in charge of the hatches enter every package that is received.

Passenger Lists. On passenger vessels, one or more passenger lists have to be prepared for each port unless all passengers are entered in the *content*, a document enumerating everything on board the ship, and all crew and passengers. Besides these papers the purser has to see that the following documents are obtained: The return list, or E.N.G., which is a list of all members of the crew who have failed to join and the names of substitutes engaged. The A.A. which is proof that the officers have the proper certificates, and the B.B. which is a sworn declaration that the last crew was properly paid. The *last light bill* gives the date up to which all light dues have been paid. The *cocket card* is a customs clearance, and the *jerking note* is a paper stating that the ship has been searched for unentered goods, and bearing a list of bonded goods on board. The *victualling bill* is a list of stores for use on the voyage, and is endorsed by the customs officials. The *port clearance* authorises the vessel to proceed to sea, and the *quarantine certificate* permits her to enter another port.

Besides preserving these papers, and having copies made by the clerks, or making them himself, the purser has to keep a register of all stores in the vessel, and of the quantities issued daily and consumed as well as of all purchases which he may make for the use of his ship. He checks the steward's wine bills, and sees that passengers accounts are properly made out and delivered weekly. He supervises the daily menus for the two saloons, and satisfies himself that the victuals served out to the crew are in good condition and are at least of the amount per man stipulated for in the articles. He makes out a list of all valuables entrusted to his care, and shows it to the captain for verification. He makes out the wages bill at the end of the voyage and enters thereon any advances that may have been made to officers or men on the journey, and at the close of the voyage he attends at the shipping office with the captain or chief officer and personally sees the crew paid off and signed off the articles. He is also expected to see that every member of the crew receives a proper discharge, and in the event of the captain not attending the shipping office he must take the discharges to that official to be endorsed with the character of each recipient.

Arranging Freights. On the voyage, should additional freight offer at a port where the owners of the vessel have no agent, the purser arranges terms of freight if authorised to do so; if not, the captain does this. All the passengers' amusements are under the control of the purser, who is expected to be a good all-round entertainer and to be a friend to all on board.

This is only a general outline of the purser's duties, for each company of steamship owners has its own traditions, to which the purser must adhere rigidly. In some, for instance, all the chief officer's stores, paints, and so forth, are under the purser's control, and he has to see to them being served out when necessary, while in other companies the purser has nothing to do with deck stores.

The assistant purser and the clerks work under the direction of the purser, and have no accurately defined duties. But when only a clerk is carried that individual has to do all the purser's duties with the exception of those which relate to victualling, those being entrusted to the chief steward.

The Steward's Staff. The steward, whether under a purser or not, keeps a record of all stores under his charge, and of the amounts issued to him or by him. This should be made up each day. He gives the cooks what is required for the daily meals, and sees that the same are properly cooked. He is responsible for the cleanliness of the saloons and cabins, and manages the lower servants. In fact, he is butler and housekeeper in one. To become a steward, the aspirant must enter as a cabin boy or under steward, and learn the household work of the ship, trusting to his own energy to gain him promotion. In most of the large companies it is now requisite for the would-be steward to show his capacity for waiting at table in a sea way before being engaged.

The prospects of stewards vary. In large companies the position of head steward is a very lucrative one, and one of great honour, while on a tramp the steward is only the captain's servant. It is impossible to lay down even an approximate scale of pay in the domestic department, for everything depends on the ship and the company it belongs to. Taken altogether, however, sea-going servants are much better paid than their colleagues ashore, and the life is full of charm.

Ships' cooks are of two classes. On liners they must be thoroughly trained chefs, capable of catering for a first-class restaurant. They have usually served an apprenticeship ashore before going to sea as an assistant cook, and then perfected themselves in the management of the floating kitchen. On tramp steamers and sailing ships the cook is an individual who has taught himself, and the dinners he serves up bear testimony to this species of training. Shipowners of to-day are at last beginning to recognise that a trained cook is less wasteful than the self-taught servant, and a movement is in progress for the bettering of this class of servant. The youth who wishes to sail as a cook will do well to obtain some good lessons ashore before he offers himself for a post, and his chances of promotion and regular work will be greatly increased thereby. Cabin stewards and waiters are really sea-going housemaids and parlourmaids.

The Engineer's Department. In this department the line is rigidly drawn between the officers and the crew, just as happens on deck. In olden days the executive officers of the steamer used to look down on the engineers, but better feeling has now sprung up, and the engineers are held to be engineer officers, and are treated as gentlemen. The training of a marine engineer is discussed on page 6366.

Greasers are the labourers of the engine-room. They act entirely under the orders of the engineer of the watch. They are expected to have had some experience ashore in engine-rooms before they ship as greasers. Their duties are varied. They have to keep the engines properly lubricated, to assist in repairs of every kind, and generally to assist in the hundred and one odd jobs which crop up in the engine-room. They have no future before them.

The firemen spend their watches in the stokehold, feeding the giant furnaces which heat the boilers. They are labourers pure and simple, though some experience is necessary before they are able to get the best value out of the coal they are using. They begin as ordinary stokers, and can eventually rise to be a leading fireman, when they will have subordinate charge of one watch of stokers. Under the foreman stoker, or leading fireman, are several trimmers, whose duty it is to enter the coal bunkers and see that the coal is properly fed down to the coal ports in the stokehold, so that the firemen can get at it to shovel it into the furnaces. When not so employed they are engaged in working the ash hoist, clearing out the waste cinders, and throwing them overboard. The coal-trimmer is the lowest servant on a steamer, and his work is both unpleasant and insanitary, the coal-dust often causing fatal lesions to the lungs.

General Ship's Routine. At regular intervals during a voyage on every vessel the crew are piped to fire stations. The exact position of every member has been apportioned by the chief officer and on the pipe going, each man, save the officer of the watch, the engineer on duty, the quartermaster, and greaser, and the principal stokers, have to run to the places assigned to them. The hoses are fitted, pumps manned, or steam pumps started, and everything made ready for suppressing an outbreak. This is practised until each member can perform his duty without the least hesitation or confusion. Similarly, boat stations are practised until each officer and man knows just where he has to take his place in a boat, and what part he has to play in the general work of saving life in case of need. Muster of all hands takes place on Sunday morning, as a rule, when the captain, chief officer, chief engineer, and purser inspect the ship's crew, and also visit the various portions of the ship to see that all is clean and in good order. On weekdays, in well-regulated vessels, the three heads of departments—chief officer, engineer, and purser—inspect the ship and report all clean and well found.

Concluding this section, we may say that the sea offers an honourable and fascinating calling to healthy men. The prospects, especially in the deck department, are good; the life is full of change and is healthy, and, taken all round, sailors are capital fellows, and make firm and loyal friends. No large fortunes can be made at sea, but the sailor can lay by enough for his old age, and he is always well fed and housed.

GREEK–LATIN & GREEK ROOTS

Being the Conclusion of the Course in Greek, Together with a List of Latin and Greek Root Words and their Derivatives

GREEK

Continued from page 6672

By G. K. Hibbert, M.A.

PROSE COMPOSITION

THE student has now arrived at a point when he should devote considerable time to turning passages of English prose into Greek. While a rough working knowledge of a language can be attained without doing much composition, it is only by means of considerable attention given to composition that an accurate knowledge can be acquired.

The student is earnestly recommended to procure Sidgwick's "First Greek Writer" (3s. 6d.), and when he has worked through this, to proceed to Sidgwick's "Greek Prose Composition" (5s.). Both these books are published by Rivingtons, and can generally be picked up at a second-hand book shop. Each contains an English-Greek vocabulary, but if the student should feel the need of an English-Greek dictionary, there is a good one by Yonge, published at 8s. 6d. by Longmans.

It is, however, advisable to rely more on the Greek-English dictionary than on the English-Greek, for the former shows us the *usage* of the Greek word, and gives us the different shades of meaning. If in turning English into Greek we cannot think of the Greek for a certain English word, we can generally think of some synonym, or recast the whole phrase so as to bring it into a form that we can translate into Greek. For example, instead of "in a state of felicity," we could say "being happy," *εὐτυχὴς ὤν*; instead of "he rejected this overture," we could say "he did not wish to do this," *οὐκ ἤθελε ταῦτα πράττειν*, and so on.

In a preceding part of this course [page 5808] we gave the fable of the frogs asking for a king; let us now render into Greek John Milton's reflections thereon:

The Fable of the Frogs: its Moral

"Nor are you happier in the relating or the moralizing your fable. 'The frogs' (being once a free nation, saith the fable) 'petitioned Jupiter for a king: he tumbled among them a log: they found it insensible; they petitioned then for a king that should be active: he sent them a crane' (a stork, saith the fable), 'which straight fell to pecking them up.' This you apply to the reproof of them who desire change: whereas indeed the true moral shows rather the folly of those who being free seek a king; which for the most part either as a log lies heavy on his subjects, without doing aught worthy of his dignity and the charge to maintain him, or as a stork is ever pecking them up and devouring them."

Before attempting to turn this into Greek we should do well to re-write it in English that is simpler and more adaptable to the Greek idiom, somewhat as follows:

"You appear neither to tell nor to understand the myth aright. For the frogs (having become free, says the story of old) asked Zeus for a king: therefore he threw down a log, which to them indeed seemed something senseless, so that they asked for an active king. Therefore he sent a crane, or which the myth says a stork, and he immediately ate them up. And this you reproach to those desiring change; but rather it wishes to tell the folly of those being free and desiring a king, who for the most part either oppresses his subjects as a log, not doing anything in accordance with his dignity and the expense of his keep, or, as a stork, always seizes them and eats them up."

Greek Version of the Above

τὸν γὰρ μῦθον οὔτε ὀρθῶς λέγειν οὔτε συνίεναι φαίνεσθε. οἱ γὰρ βάτραχοι (λέγει τὸ πρὶν, ἐλεύθεροι γενόμενοι) τὸν Δία βασιλέα ᾐτήσαντο· ξύλον οὖν κατέβαλεν, ὃ αὐτοῖς ἀναίσθητον δή τι ἔδοξεν, ὥστε βασιλέα αἰτεῖσθαι καρτερόν. γέρανον οὖν ἔπεμψεν (ἢ ὃν ὁ μῦθος λέγει πελαργόν), ὁ δὲ εὐθὺς κατήσθιεν αὐτούς. καὶ ταῦτα τοῖς μεταβολῆς ἐπιθυμοῦσιν (dative plural of present participle of *ἐπιθυμέω*, governs genitive) *ὀνειδίζετε. ἀλλὰ μᾶλλον βούλεται μωρίαν λέγειν τὴν τῶν ἐλευθέρων ὄντων* (present participle of *εἰμί*) *καὶ βασιλέως ἐπιθυμούντων, ὅσπερ ἐπὶ τὸ πολὺ ἢ ὡς ξύλον βαρύνει τοὺς ὑπηκόους οὔτι πρὸς τὸ ἀξίωμα καὶ τὴν τῆς τροφῆς δαπάνην ποιῶν, ἢ ὡς πελαργὸς ἀεὶ καταλαμβάνει αὐτοὺς καὶ κατεσθίει.*

NOTE. As an exercise, the above might be translated back again into English after the lapse of a few days from the first reading.

General Concluding Remarks. Greek differs from English, French, German, and most modern tongues, in its greater simplicity of expression. It puts things in a direct and concrete form without artificiality and allusiveness. Thus: 1. Where we think of a man as a person, a complex set of attributes, the Greeks would either think of him as a body, a visible and palpable object, or they would denote him by some obvious part of his body—*e.g.*, head, face, or breast, as *ὦ φίλτατον κάρα*, O dearest head.

2. Where we talk of an abstraction, they talk of a thing. Thus the Greeks constantly use the neuter adjective with the article in place of an abstract noun—*e.g.*, *τὸ καλόν*, honour; *τὸ ὠφέλιμον*, utility. So a complex abstract idea is

expressed as two ideas—*e.g.*, *προαίρεσις καὶ πολίτεια*, political principles; *πρᾶξις καὶ συμμαχία*, negotiations for alliance.

3. The Greeks possessed a great love of moderation and of the due mean, as opposed to anything strained or extravagant (*cf.* their use of *εἰ* instead of *ὅτι* after *θαυμάζω, αἰσχύνομαι, κ.τ.λ.*). They did not borrow from other tongues when a native word would do. In this respect no cultivated tongue is so pure as Greek, which in classical times had only 2½ per cent. of loan words, compared with 14 per cent. in Latin. Greek is also sparing of the use of metaphors; hence expressions like "They cast about," "Night drew on," "He became a laughing stock," "On the field of battle," "Silence reigned," must be translated into Greek without the metaphor—thus: *ἐσκόπουν, νὺξ ἐπῆλθε, γελοῖος ἐγένετο, μαχόμενος, ἐν ἡσυχίᾳ ἦν*.

As to Syntax, we may note that:

1. Greek is the richest of all languages in particles—according to Aristotle the one nicety that no barbarian could master! Every sentence unless beginning a treatise, or because of vividness, is joined to a previous one by a connective particle, while in English the sequence of thought is left to be gathered from the arrangement of the clauses.

2. The Greek verb system is far richer than Latin, and can express many more shades of meaning. It has preserved many forms of the original verb of the parent speech—*e.g.*, the dual, the middle, and the aorist as distinct from the perfect. Very interesting is the Greek use of the aorist. In the indicative mood it does generally denote *past* time, but in all other moods the aorist has no connotation of "past." In these other moods the aorist regards the act as a single occurrence, not considering it as protracted, while the present regards the act as extended in time. Examples: *νοσῆσαι*, to fall sick; *νοσεῖν*, to be sick. *πεῖσαι*, to prevail; *πείθειν*, to urge. *εὐτυχῆσαι*, to get a stroke of luck; *εὐτυχεῖν*, to enjoy continued good luck.

In the indicative, the aorist is constantly used where we should use the pluperfect. In fact, the pluperfect is seldom used in Greek, while the aorist can hardly be used too frequently.

We may here note an idiomatic use of the present tense, an idiom which is found also in French, to denote that the act or practice described extends from the past up to the present time—as: *πάλαι προσδοκῶ*, I have been waiting a long time; *τρία ἤδη ἔτη νοσῶ*, I have been ill these three years.

3. Greek prefers a personal to an impersonal construction. Thus, for "It is right for me to do it," they say *δίκαιός εἰμι ποιεῖν*, I am right to do it; also *δίκαιός ἐστιν ἀπολωλέναι*, It is right that he should be hung; *φανερός εἰμι ποιῶν*, It is plain that I am doing it. So from *μέλει μοι*, it is a care to me, comes *μέλω*, I care for; from *δοκεῖ μοι*, it seems to me, comes *δοκῶ*, I think, *or*, I think it best; from *δεῖ*, it lacks, comes *δέω*, I lack, and so on (*cf.* "I am well" for "it is well with me," and "if you please" for "if it please you").

The Order of Words

In English the order of speech is as a rule the same as the order of thought; only occasionally is it changed to emphasise some particular word (*e.g.*, "He saved others, Himself he cannot save"). In Greek, which is a highly inflexional language, the termination of the word generally shows whether it is subject or object, and so the order is much freer, and depends much more on emphasis than on the order of thought. The emphatic word is put first or last in the sentence. In Latin, as in modern German, the verb is mostly considered the emphatic word, and is put at the end; but this is not so in Greek. The order of words in Greek is far more natural than in Latin, being almost as natural as in English; above everything the Greeks avoided artificiality. In English, when any two words are opposed to other two words, the same order is kept in both clauses, but in Greek the order of the second clause is usually reversed—*e.g.*, *τὰς πρῴρας μὲν ἔξω, εἴσω δὲ τὰς πρύμνας* (Thuc. II, 83). This is called *Chiasmus*.

For the sake of clearness the Attic orators often put the relative clause before that which contains the antecedent; this is done very frequently by Demosthenes—*e.g.*, *περὶ ἃ ἑκάτεροι σπουδάζετε, ταῦτ' ἄμεινον ἑκατέροις ἔχει*, Each of you is superior in the points in which you respectively take most interest; *ἃ δὲ νῦν ἀποκρινάμενοι τὰ δέοντ' ἂν εἴητ' ἐψηφισμένοι, ταῦτ' ἤδη λέξω*, I will tell you now what you should answer so as to arrive at the proper decision.

Greek is *par excellence* the language of *naturalness* and of *clearness*; if we read it, it cannot fail to clarify our thinking; if we write it, it will both simplify and dignify our style.

Key to Translation, page 6672

κώνωψ πρὸς λέοντα ἦλθε καὶ ἔλεγεν· ʼΟὔτε φοβοῦμαί σε, οὔτε ἰσχυρότερός μου εἶ· τίς γάρ σοί ἐστιν ἡ δύναμις; ξύεις τοῖς ὄνυξι καὶ δάκνεις τοῖς ὀδοῦσι; τοῦτο καὶ γυνὴ τῷ ἀνδρὶ μαχομένη ποιεῖ. ἐγὼ δὲ πολύ εἰμί σου ἰσχυρότερος, καὶ εἰ θέλεις, ἔλθωμεν καὶ εἰς πόλεμον.' καὶ ὁ κώνωψ ἔδακνε τὰ τοῦ λέοντος ἄτριχα πρόσωπα περὶ τὰς ῥῖνας. ὁ δὲ λέων τοῖς ἰδίοις ὄνυξιν ἔξυεν ἑαυτὸν, ἕως οὗ ἠγανάκτησεν· οὕτως ὁ κώνωψ ἐνίκησε τὸν λέοντα καὶ ἀπῆλθεν. ἔπεσε (from *πίπτω*) *δὲ εἰς τὸν ἀράχνης δεσμὸν καὶ ἀπωδύρετο* (from *ἀποδύρομαι*), *ὅτι ἐνίκησε λέοντα, ἰσχυρότατον θῆρα, ἀλλ' ἀπώλετο* (from *ἀπόλλυμι*) *ὑπὸ εὐτελοῦς ζώου, τῆς ἀράχνης.*

As practice in translation, the student might after a lapse of a few days write out the above in English.

NOTE. For the treatment of accents the student is referred to Rutherford's or Goodwin's Greek Grammar (Macmillan).

GREEK *concluded*

TABLE OF ROOT WORDS IN LATIN AND GREEK

With their Derivatives in English, French, Italian and Spanish.

By G K. Hibbert, M.A.

In English, French, Italian and Spanish, a great many words derived from the same Latin or Greek root-word undergo changes more or less consistent in all four languages Consequently, as a general rule, when we know the English word derived from the Latin or Greek, we can construct the corresponding word in French, Italian or Spanish, Below are set forth the most common rules in this connection These should be carefully noted, as in the list which we are giving only the *exceptions* to these rules will be noted That is to say, only when a word of Greek or Latin origin undergoes an irregular change in any of the other languages will that word be given. This will save the needless repetition of numerous words which the student, with these rules before him, can form for himself

It should be mentioned that German is not included in this list because German is largely Teutonic in its structure, and not (like French, Italian and Spanish) of Classical or Romance origin

The following scheme gives the principal rules for the respective languages, the English word being taken as the basis in each case

Nouns

A. Greek Derivatives

English Ending	*French*	*Italian*	*Spanish*
y	ie	ia	ia
(agony)	(agonie)	(agonia)	(agonia)
e	e	a	a
(parable)	(parable)	(parabola)	(parabola)
a	e	a	a
(asthma)	(asthme)	(asma)	(asma)
t, l, m, and most consonants	add e	add o	add o
ics	ique	ica	ica
(mechanics)	(mecanique)	(meccanica)	(mecanica)
ch	que	ca	ca
(monarch)	(monarque)	(monarca)	(monarca)
is	e	i	is
(crisis)	(crise)	(crisi)	(crisis)

B. Latin Derivatives

tor, sor, or, our, er	eur	ore	or
(doctor, emperor)	(docteur, empereur)	(dottore, imperatore)	(doctor, emperador)
ary	aire	ario	ario
(lapidary)	(lapidaire)	(lapidario)	(lapidario)
ate	at	ato	ado
(legate)	(legat)	(legato)	(legado)
age	age	ggio	aje
(voyage)	(voyage)	(viaggio)	(viaje)
ty	té	tà	dad
(vanity)	(vanité)	(vanità)	(vanidad)
ion	ion	ione	ion
(action)	(action)	(azione)	(accion)
ain	agne	agna	aña
(mountain)	(montagne)	(montagna)	(montaña)

Adjectives

A. Greek Derivatives

English Ending	*French*	*Italian*	*Spanish*
ic	ique	ico	ico
(cosmetic)	(cosmetique)	(cosmetico)	(cosmetico)
ac	aque	aco	aco
(maniac)	(maniaque)	(maniaco)	(maniaco)
an	e	a	a
(cosmopolitan)	(cosmopolite)	(cosmopolita)	(cosmopolita)

B. Latin Derivatives

al	al	ale	al
(general)	(général)	(generale)	(general)
ain	ain	o	o
(certain)	(certain)	(certo)	(cierto)
ar	ier	are	ar
(singular)	(singulier)	(singolare)	(singular)
ary, arious	aire	ario	ario
(gregarious, necessary)	(grégaire, nécessaire)	(gregario, necessario)	(gregario, necesario)
ian	ien	iano	iano
(Christian)	(Chrétien)	(Cristiano)	(Cristiano)

(terrestrial, equestrian)	(terrestre, equestre)	(terrestre, equestre)	(terrestre, ecuestre)

Verbs

A Greek Derivatives

English Ending	*French*	*Italian*	*Spanish*
ise, ize	iser	are	ar
(baptize)	(baptiser)	(battezzare)	(bautizar)

B Latin Derivatives

fy	fier	ficare	ficar
(edify)	(edifier)	(edificare)	(edificar)
ish	ir	ire	ir
(nourish)	(nourrir)	(nutrire)	(nutrir)
—	er	are	ar
	(demander)	(demandare)	(demandar)
—	re	ere	er
	(croire)	(credere)	(creer)
—	ir	ire	ir
	(vêtir)	(vestire)	(vestir)

There are, of course, many changes at the beginning or in the middle of words as they pass from one language to another, but these cannot be noted here in full A study of the following list will make the majority of these changes clear

Latin

(Note *F*—French, *I*=Italian, *S*=Spanish)

Acer, *sharp;* Acuo, *I sharpen:* acid, acrid, acrimonious, acute, acumen, acerbity, vinegar (sour wine). *F* âcre, aigu, aigre. *I* acre. *S* agudo.

Ædes, *house*. edify, edifice (facio = I make)

Æquus, *level* · equal, equity, equator, equivalent, equinox, adequate. *F* égal, équateur *I* uguale, equinozio. *S* igual, ecuador, equinoccio.

Æstimo, *I value* · estimate, esteem, aim. *I* stima (= esteem, noun).

Ævum, *age* · coeval, primeval.

Ager, *field:* agriculture, agrarian. *I* agrimensore (land-surveyor). *S* agrimensor.

AGO, *I drive, I do:* act, agent, agile, agitate, exigent, cogent, cogitate, litigation. *F* agir (to act). *I* atto (an act). *S* accion.

ALBUS, *white*: album, albumen, Albion, albino. *F* aube (alb). *I* albeggiante (whitish). *S* albar.

ALIUS, *other;* ALTER (*the other of two*): alias, alibi, alien, alter, alternate, "alter ego," altruism. *F* autre. *I* altrui, altrove, altramente. *S* otro.

ALTUS, *high, deep:* alto, altitude, exalt. *F* altier (haughty). *I* alto, altura, altero. *S* alto, altivo.

AMBULO, *I walk:* amble, perambulator, somnambulist, ambulance. *I* amb.o. *S* amblar.

AMO, *I love:* amour, amorous, amateur, amatory, amicable, inimical, amiable, amenity. *F* aimer. *I* amore. *S* amor, amigo.

ANGO, *I choke:* anger, anguish, anxiety, angina pectoris. *F* angoisse. *I* angore, ansieta. *S* ansia.

ANIMA, *breath:* animal, animate. ANIMUS, *mind:* animadvert, magnanimous, unanimous.

ANNUS, *year*: annual, annuity, anniversary, millennium, perennial, biennial, centenary, solemn. *F* année. *I* anno, perenne. *S* año.

APERIO, *I open:* April, aperture, aperient. *F* Avril, apéritif. *I* Aprile, apritivo, apriporta (door-opener). *S* Abril, abertura.

AQUA, *water:* aquarium, aquatic, aqueduct. *F* eau, aquarelle (painting in water-colours). *I* acqua, acquidotto. *S* agua.

ARDEO, *I burn:* ardent, arson, ardour.

ARTUS, *a joint:* article (a little joint), articulate. *I* articolo. *S* articulo.

AUDEO, *I dare:* audacious. *S* audaz.

AUDIO, *I hear:* audience, audible, audit. *F* auditoire, audition. *I* udire. *S* oir.

AUGEO, *I increase:* augment, auction, author, authority. *F* auteur, octroi. *I* aumentare, autore.

AURIS, *ear:* aurist, auricular. *F* oreille. *I* orecchio. *S* oreja.

AURUM, *gold:* auriferous, aureole, oriole, oriel. *F* or. *I* oro. *S* oro.

AVIS, *bird:* aviary, auspicious (auspice = avispicium, drawing an omen from watching birds).

BARBA, *beard:* barb, barber, barbel. *F* barbon (grey-beard, dotard). *I* barbone.

BELLUM, *war:* duel (original form of *bellum* was *duellum*), bellicose, belligerent, rebel, revel. *F* belliqueux. *I* ribelle. *S* belico.

BENE, *well:* benefit, benign, benediction, benevolence.

BIS, *twice:* biscuit, bi-sect, bi-furcate, biceps, binocle, binomial, combine. *F* bis (encore !).

BONUS, *good:* bon-bon, bonny, bonus. *F* bien, bon. *I* bene, buono. *S* bien, bueno.

BREVIS, *short*: brief, brevity, breviary, semibreve, brevet. *F* bref. *I* and *S* breve.

CADO, *I fall*: cadaverous, cadence, cascade, chance, case, casual, casuistry. ac-cident, oc-cident, oc-casion. *F* cas. *I* and *S* caso. *S* caer (to fall).

CÆDO, *I cut, I kill:* homicide, suicide, incision, concise, circumcision.

CÆLUM, *heaven, sky:* celestial, ceiling. *F* ciel. *I* and *S* cielo.

CANDEO, *I shine:* candid (= white), candidate (at Rome applicants for office dressed in white), candle, in-cendiary. F chandelle, incendie (fire). *I* and *S* candela, incendio.

CANO, *I sing:* chant, incantation, recant, canticle, cantata, canto. *F* chanter. *I* cantare.

CAPIO, *I take:* captive, caitiff, capable, capacity, accept, receptive, receive, conceit, capstan. *F* recevoir, cabestan. *I* cattivo, ricevere. *S* cautivo, recibir.

CAPUT, *head:* capital, cape, capitulate, captain, chief, chapter. *F* capitaine, chef, chapitre. *I* capitano, capo, capitolo. *S* capitan, cabeza, capitulo.

CARO (gen. *carnis*), *flesh:* carnage, carnal, carnation, incarnation, carnival, carnivorous. *F* chair. *I* and *S* carne.

CAUSA, *cause:* cause, excuse, accuse, recusant.

CEDO, *I go, I yield:* cede, cession, recede, abscess, success. *F* céder. *I* cedere.

CENTUM, *a hundred*: cent, century, centipede. *F* cent, centime. *I* cento, centinaio. *S* ciento.

CERNO, *I distinguish:* discern, concern, discreet, secret (from the supine *cretum*). *I* segreto.

CHARTA, *paper:* chart, charter, card, carte, cartoon, cartridge. *F* carte. *I* and *S* carta.

CIVIS, *citizen:* civic, civil, city. *F* cité, citoyen. *I* citta. *S* ciudad.

CLAMO, *I shout:* clamour, claim, proclaim, reclaim. *I* chiamare, clamare (to call).

CLARUS, *bright:* clear, claret, clarion, clarify. *F* clair. *I* chiaro.

CLAUDO, *I shut:* clause, close, closet, cloister, include, conclude, preclude. *F* clos, cloître. *I* chiuso, chiostro. *S* claustro.

COLO, *I till:* cult, culture, cultivate, colony. *I* and *S* culto (worship).

CONTRA, *against:* country, counter, counterfeit, countermand, contrast, contrary, contradict.

COQUO, *I boil:* cook, concoct, decoction. *I* cuoco. *S* cocinero.

COR, *heart:* cordial, concord, record. *F* cœur. *I* cuore. *S* corazon.

CORPUS, *body:* corporation, corps, corpse, corpulent, incorporate, corporal. *I* corpo. *S* cuerpo.

CREDO, *I believe:* creed, credit, incredible. *F* croire, croyance. *I* credo, credenza. *S* creer.

CRESCO, *I grow* (supine, *cretum*): crescent, increase, concrete, recruit. *F* croître, croissant. *S* crecer.

CRUX, *cross:* crucial, crucible, crucifix, crusade, *F* croix, croisade. *I* croce, crociata. *S* cruz.

CURA, *care:* cure, curate, curator, curious, sinecure, procure, proctor (= procurator), secure, sure. *S* cuidado.

CURRO, *I run:* cursive, cursory, current, corridor, curriculum, course, discourse, concourse, concur, recur, incur. *F* courir. *I* correre. *S* correr.

DEBEO, *I owe:* debit, debt, due, duty, debenture. *F* devoir, dette. *I* dovere, debito. *S* deber.

DECEM, *ten:* December, decimal, decimate. *F* dix. *I* dieci. *S* diez.

DENS, *tooth:* dent, dentist, trident. *S* diente.

DEUS, DIVUS, *god:* deity, deify, divine, divinity. *F* dieu. *I* dio. *S* dios.

DICO, *I say:* diction, dictate, predict, contradict. *F* dire. *I* dire. *S* decir.

DIES, *day:* diary, diurnal, quotidian, adjourn, journal, journey. *F* jour. *I* giorno. *S* dia.

DIGNUS, *worthy:* deign, dignity, disdain, condign. *I* degno.

DO, DONO, *I give, I put.* donation, con-done, pardon, date, add (ad-do), e-dit. *F* donner. *I* dare.

DOCEO, *I teach:* docile, document, doctor, doctrine. *I* dottore.

DOMINUS, *lord:* dominate, domain, dame (= domina), domino, dominie. *F* dimanche (=dies dominica, the Lord's Day). *I* domenica. *S* duenna.

DOMUS, *home:* domicile, domestic, dome.

DORMIO, *I sleep:* dormant, dormouse, dormitory.

DUCO, *I lead:* duke, duct, educate, conduce, reduction. *F* duc, conduire. *I* duca, condurre. *S* duque, conducir.

DULCIS, *sweet:* dulcet, dulcimer. *F* doux. *I* dolce. *S* dulce.

DUO, *two*: duet, dual, dubious, doubt. *F* deux. *I* due. *S* dos.

EMO, *I buy,* SUMO, *I take,* (sub-emo): redeem, exempt, ransom, consumption, presume, assume.

Eo, Itum, *I go:* exit, exeunt, transit, trance, issue, itinerate, obituary, initial, perish. **Comes** = companion, one who goes with: count, concomitant.

Equus, *horse:* equine, equestrian.

Faber, *workman:* fabric, fabricate, forge. *I* fabbro (forger).

Facio, *I make:* fact, feat, faction, face, superficial, defeat, infect, comfit, confectioner, fortify, defy, efficient. *F* faire, fait. *I* fare, fatto. *S* hacer, hecho.

Fallo, *I deceive:* false, infallible, falter, fail, fall, fault. *F* faillir, faux. *S* faltar.

Fero, *I bear* (supine *latum*): fertile, suffer, transfer, translate, legislate, dilate, confer, vociferous. *I* trasferire.

Ferveo, *I boil:* fervent, ferment, effervesce. *S* hervir.

Fido, *I trust:* fidelity, fiduciary, confide, perfidy, defy. *F* foi (faith). *I* fede. *S* fe.

Fingo, *I shape:* fiction, feign, figure. *F* feindre. *I* finzione. *S* ficcion.

Finio, *I end:* fine, final, finish, finite, infinite, define, infinitive.

Fiscus, *purse, treasury:* fiscal, confiscate.

Flagro, *I burn:* flagrant, conflagration, flame, inflammation. *I* fiamma. S flama.

Flo, *I blow:* flatulent, inflate. *F* enfler. *I* enfiare.

Flos, *flower:* florid, florist, flourish, flour, efflorescence. *F* fleur. *I* fiore. *S* flor.

Fluo, *I flow:* fluid, flux, fluctuate, fluent, affluent, confluence, influence, influx.

Fœdus, *a treaty* (akin to fides, *faith*): federal, federation, confederate.

Folium, *leaf:* foil, foliage, folio, trefoil. *F* feuille. *I* foglia. *S* hoja.

For, Fans, Fatum, *I speak:* fame, infamous, fate, fatal, infant, confess, nefarious.

Fortis, *strong:* fort, fortress, forte, fortify, fortitude, comfort. *S* fuerte.

Frango, *I break:* fragment, fracture, fraction, fragile, frail, infraction, refraction, infringe.

Frater, *brother:* friar, fraternity, fraternal, fratricide. *F* frère. *I* fratello, fra.

Frons, *brow:* front, frown, affront, confront, frontage, frontier, frontispiece.

Fruor, *I enjoy:* fruit, fruition, frugal, usufruct. *I* frutto. *S* fruto.

Fugio, *I flee:* fugitive, fugue, refuge, subterfuge. *F* fuir. *I* fuggire. *S* huir.

Fundo, *I pour:* funnel, foundry, confound, confuse, refund; refuse, fuse, futile, fountain, font.

Fundus, *bottom:* fund, fundamental, foundation. *F* fond. *I* and *S* fondo.

Fungor, *I perform:* function, perfunctory.

Gelo, *I freeze:* gelid, gelatine, galantine, jelly, congeal. *F* gelée. Also **Glacies**, *ice:* glacier, glacé, glass. *I* ghiaccio (ice). *S* hielo.

Gero, *I bear:* gerund, gesture, gesticulate, jest, suggest, digest, vice-gerent, belligerent, register.

Gradior, *I step:* grade, graduate, gradual, digress, transgress, egress, aggression, degrade, degree.

Gravis, *heavy:* grave, gravid, gravity, grief.

Grex, *flock:* gregarious, egregious, congregation. *I* gregge.

Gusto, *I taste:* gusto, disgust. *F* goût. *I* and *S* gusto.

Habeo, *I have:* habit, have, exhibit, inhibit, prohibit. *F* avoir. *I* avere. *S* haber. Also a frequentative form, **Habito**, *I dwell:* inhabit, habitation, haunt, cohabit.

Hæreo, *I stick:* adhesive, hesitate, cohere.

Homo, *man:* homicide, human, humane, humanity. *F* homme. *I* uomo. *S* hombre.

Horreo, *I bristle:* horrid, horror, horrible, abhor.

Hospes, *guest:* hospital, hospice, hospitable, host, hostel, hotel. *I* ospedale. *S* huesped.

Hostis, *enemy:* host, hostile. *S* hueste.

Humeo, *I am moist:* humid, humour.

Humus, *ground:* humble, humiliate, exhume. *I* umile. *S* humilde.

Idem, *same:* identity, identify, identical.

Ira, *anger:* ire, irascible, irate.

Jacio, *I throw:* ejaculate, object, reject, adjective, conjecture, projectile, jet, jetsam. *F* jeter. *I* gettare. *S* echar.

Judex, *judge:* judicial, adjudicate, prejudice. *F* juge. *I* giudice. *S* juez.

Jungo, *I join:* juncture, junction, joint, conjunction, injunction. *F* joindre. *I* giungere. *S* juntar.

Juro, *I swear:* jury, conjure, adjure, perjury. *I* giuri. *S* jurado.

Jus, *law:* just, jurisdiction, jurisprudence, injure. *I* giusto.

Juvo, *I help:* adjutant, jury (mast).

Labor, *I glide:* lapse, collapse, relapse.

Lædo, *I hurt:* lesion, elide, collide, lèse-majestie.

Lapis, *stone:* lapidary, lapis lazuli, dilapidate.

Lavo, *I wash:* lave, lavatory, lotion, lava, lavender, lavish, laundry. *F* laver. *I* lavare.

Lego, *I gather, I choose, I read:* neglect, collect, elect, intelligent, lecture, lesson, college, legion, legend, legible. *F* lire. *I* leggere. *S* leer.

Lego, *I depute:* legacy, legatee, legation, relegate. *F* legs.

Leo, *lion:* leonine, leopard, Leonard, Leander.

Levo, *I lift:* levity, levy, Levant, elevator, levée, lever, relieve, alleviate, legerdemain.

Lex, *law:* legal, legitimate, legislate, privilege. *F* loi. *I* legge. *S* ley.

Ligo, *I bind:* religion, obligation, league, ligature, ligament, colligate. *F* lier. *I* legare.

Linquo, *I leave:* delinquent, relinquish, relict, derelict.

Litera, *letter:* literal, literary, literature, illiterate. *F* lettre. *I* lettera. *S* letra.

Locus, *place:* local, locate, locomotive, locum tenens. *F* lieu. *I* luogo. *S* lugar.

Loquor, *I speak:* eloquent, colloquy, loquacious, elocution, magniloquent, soliloquy.

Luceo, *I shine:* lucid, elucidate, lucent, lunar, lunatic, luminary, illumine. *F* luire. *I* lucere.

Ludo, *I play:* elude, prelude, delude, collusion, illusion, ludicrous.

Magnus, *great:* main, magnate, magnify, magnitude, majesty, major, mayor, magistrate, master. *F* maire, maître *I* and *S* maestro.

Malus, *bad:* malady, malaise, mal-de-mer, malaria, malefactor, malevolent, maltreat, malice, malignant, malinger.

Maneo, *I remain:* mansion, manse, manor, menial, remain, remnant, permanent. *F* maison.

Manus, *hand:* manual, manufacture, manuscript, manicure, manifest, manipulate, manœuvre, emancipate, maintain. *F* main. *I* and *S* mano.

Mater, *mother:* maternal, matricide, matriculate, matrimony, matron. *F* mère. *I* and *S* madre.

Medeor, *I heal:* medicine, medicate, remedy. *F* médecin (doctor). *I* medico.

Medius, *middle:* median, mean, medium, meridian, medieval, mediocre, Mediterranean, immediate. *F* moyen, milieu. *I* mezzo.

Memor, *mindful:* memoir, memorable, memory, commemorate, remember.

Metior, Mensus, *I measure:* mensuration, commensurate, immense. *I* misurare. *S* medir.

Miles, *soldier:* military, militia, militant, militate. *S* militar.

MILLE, *thousand*: mile, millennium, million, millimetre. *F* and *S* mil. *I* mille.

MINUO, *I lessen*: minus, minor, minim, minimise, diminish, minute, minister, minstrel, minuet, minutiæ. *F* moins, menu. *I* minore. *S* ménos.

MIROR, *I wonder at, I admire*: mirror, mirage, miracle, admire, marvel.

MITTO, *I send, I put*: mission, missile, missive, admit, permit, remiss, omit, promise, demise. *F* mettre. *I* mettere.

MONEO, *I warn*: monitor, monster, monument, demonstrate, remonstrance, admonish, summon.

MONS, *mountain*: mount, mound, surmount, amount, promontory. *F* montagne. *I* montagna. *S* monte.

MORIOR, *I die*: moribund, mortal, mortuary, mortgage, mortify, mortmain. *F* mourir. *I* morire.

MOVEO, *I move*: motion, motor, mobile, mob, moment, motive, emotion, promote, mutiny. *F* mouvoir. *I* muovere.

MULTUS, *many*: multiply, multitude, multifarious. *I* molto. *S* mucho.

MUTO, *I change*: mutation, mutable, permutation, commute, mutual.

NASCOR, *I am born*: nascent, renaissance, native, nature, nation, natal, Noel, cognate. *F* naître, née. *I* nascere. *S* nacer.

NAUTA, *sailor*: NAVIS, *ship*: nautical, nautilus, navy, navigate, navvy. *F* navire. *I* and *S* nave.

NEGO, *I deny* (nec, *not*: aio, *I affirm*): negative, negation, renegade, runagate.

NEPOS, *grandson*: nephew, nepotism. *F* neveu. *I* nipote.

NOCEO, *I hurt*: noxious, nocuous, noise, innocent, obnoxious. *F* nuire. *I* nuocere.

NOMEN, *name*: NOSCO, *I know*: NOBILIS, *known, noble*: noun, nominate, nomenclature, nominal, binomial, ignominy, gnostic, note, notion, notice. *F* nom, con-naître. *I* nome, conoscere. *S* nombre.

NOVUS, *new*: novel, novelty, novice, innovation, renovate, nuncio, announce. *F* neuf, nouveau. *I* nuovo. *S* nuevo.

NUBO, *I marry* (lit. *I veil myself*, connected with nubes = cloud): nuptial, connubial. *F* noces. *I* nozze. *S* nucias.

OCTO, *eight*: octogenarian, octave, October. *F* huit. *I* otto. *S* ocho.

OCULUS, *eye*: oculist, binocular, ocular. *F* œil, aveugle. *I* occhio. *S* ojo.

OMNIS, *all*: omnivorous, omnipotent, omniscient, omnibus, "omnium-gatherum." *I* ognuno.

OPTIMUS, *best*: optimist, optimates, "Senior Op." (at Cambridge). *I* ottimo.

OPTO, *I choose*: option, adopt, co-opt, optative.

OPUS, *work*: opera, operate, co-operative. *F* œuvre. *S* obra.

ORBIS, *circle*: orb, orbit, exorbitant.

ORDO, *rank*: ordinary, order, ordain, ordinance.

ORIOR, *I rise*: orient, origin, abortion.

ORO, *I speak, I pray*: oral, oracle, orison, oration, peroration, inexorable, adore.

OVUM, *egg*: oval, ovary, oviparous, ova, ovule. *F* œuf. *I* uovo. *S* huevo.

PANDO, *I spread*: pace, pass, passenger, expand, expanse, compass. *F* pas. *I* passo. *S* paso.

PANGO, *I fix*: pagan (from pagus = district), peasant, page, pageant, compact, impact, impinge. *F* païen, pays, paysan. *I* paese (country). *S* país.

PAR, *equal*: peer, pair, umpire, compare, compeer, parisyllabic. *F* pair, pareil. *I* pari.

PAREO, *I come forth*: appear, apparent, apparition.

PARIO, *I bring forth*: parent, parturition, oviparous, viviparous, viper, repertory.

PARO, *I make ready*: pare, parry, prepare, repair.

PARS, *part*: parse, partial, participate, particular, particle, participle, partisan, partition, party, repartee, impart, portion.

PASCO, *I feed*: pastor, pasture, repast. *F* paître.

PATER, *father*: paternal, patron, parricide, patriarch, patrimony, patriot, expatriate. *F* père. *I* and *S* padre.

PATIOR, *I suffer*: patience, passion, passive.

PELLO, *I drive*: push, pulse, compel, impel, repel, impulsive, repulsive. *F* pousser.

PENDEO, *I hang, I weigh*: pensive, pension, pendant, pendulum, suspense, depend, compensate, recompense, perpendicular, pound, ponder, poise.

PES, *foot*: pedal, pedestrian, pedestal, biped, impede, expedite, expedient. *F* pied. *I* piede. *S* pié.

PETO, *I seek*: petition, petulant, compete, appetite, repeat.

PLACEO, *I please*: plea, placid, placable, pleasant, complacent. *F* plaire. *I* piacere.

PLAUDO, *I clap, I praise*: plaudit, plausible, applaud, explode.

PLEO, *I fill*: plenary, plenipotentiary, plenty, replenish, replete, complete, supply, supplement, complement. *F* plein. *I* pieno. *S* lleno.

PLICO, *I fold*: ply, pliable, pliant, plight, apply, duplicate, double, duplicity, complicate, complex, supplicate. *F* plier. *I* piegare. *S* plegar.

PLUS, *more*: plural, pluperfect, surplus.

PONO, *I place*: post, position, positive, posture, deponent, deposit, composition, supposition, impost, compound, postpone.

POPULUS, *people*: population, popular, public, publish. *F* peuple. *S* pueblo.

PORTO, *I carry*: porter (= one who carries; but porter = doorkeeper, is from porta = door), port (= demeanour), portfolio, export, important.

POSSUM (potis-sum), *I am able*: possible, posse, potent, potentate, impotent.

POTO, *I drink*: potation, potable, potion, poison. *I* potare.

PREHENDO, *I grasp*: prehensile, apprehend, comprehensive, comprise, prison, prize (= reward). *F* prendre.

PREMO, *I press*: express, oppress, impress, print.

PRETIUM, *value*: price, precious, prize (= valuation, estimate). *F* prix. *I* prezzo. *S* precio.

PRIMUS, *first*: prim, prime, primate, premier, primeval, primrose, primitive, prince, principal, principle. *F* premier. *I* primo.

PUNGO, *I prick*: puncture, pungent, point, pounce, expunge, punctilious, punctual, punctuate.

PUTO, *I cut, I think*: putative, amputate, compute, count, reputation, deputy.

QUÆRO, *I seek*: query, quest, question, require, exquisite, inquisition. *S* cuestion.

QUATIO, *I shake* (in compounds cutio, cussum): quash, discuss, concussion, percussion.

QUOT, *how many*: quote, quotient, quota, quotidian. *S* cociente.

RAPIO, *I snatch*: rapacious, rape, rapid, rapine, rapt, rapture, ravage, ravish, ravenous, ravine. *F* ravir. *I* rapire.

REGO, *I make straight, I rule*: regent, regal, royal, regnant, reign, regicide, regiment, regular, rector, rectify, direct, correct. *F* roi (king). *I* re. *S* rey.

ROGO, *I ask*: rogation, derogatory, arrogate, abrogate, interrogative, prorogue

RUMPO, *I break*: rupture, eruption, corrupt, disruption, bankrupt, abrupt, interrupt. *F* rompre. *I* rompere.

SAL, *salt*: salad, saline, salary, sausage. *F* sel. *I* sale. *S* sal.

Salio, *I leap:* salient, sally, salmon, assail, assault, insult, exult, result. *F* saillir. *I* saltare

Salus, *health:* salute, salutary, salubrious, salvation, salvage, saviour, safe, save, sage (the plant). *F* sauf (= safe). *I* salvo.

Sapio, *I taste:* savour, sapient, sage (= wise), insipid. *I* sapere. *S* sapido (= high-flavoured).

Scio, *I know:* science, omniscient, conscious.

Scribo, *I write:* scrip, script, scripture, scribe, describe, conscription, postscript, scribble, scrivener. *F* écrire, escritoire. *I* scrivere. *S* escribir.

Seco, *I cut:* section, sect, dissect, bisect, segment, insect, intersect.

Sedeo, *I sit:* sediment, sedentary, session, possess, sedate, sedulous, preside, *F* as-seoir.

Senex, *old man:* senile, senior, sir, sire, senate. *F* sieur. *I* signore. *S* señor.

Sentio, *I feel:* sense, sentient, sentence, sentiment, assent, consent, scent.

Sequor, *I follow:* sequence, sequel, sequestrate, consequence, consecutive, persecute, second, sue, suit, pursuit. *F* suivre, suite. *I* seguire. *S* seguir.

Sero, *I join:* series, serial, sermon, insert, desert, exert, assert.

Servio, *I serve:* serf, servile, servant, sergeant, dessert, deserve.

Similis, *like:* **Simul**, *at the same time:* similar, simile, simulate, simultaneous, assimilate, semblance, resemble. *F* sembler.

Solvo, *I loosen, I pay:* solve, solvent, soluble, solution, dissolute, absolute, resolve.

Sono, *I sound:* sonorous, sonata, sonnet, resonant, consonant, unison, person, parson. *F* sonner.

Specio, *I look:* spy, species, specious, special, spice, specimen, specify, spectacle, spectre, speculate, aspect, respect, conspicuous, perspective, suspicion, prospectus, despise. *F* épier. *I* specchiare. *S* espiar.

Spiro, *I breathe:* spirit, spirant, aspirate, conspire, inspiration, respirator, perspire.

Spondeo, *I pledge:* sponsor, spouse, responsible, despond. *F* épouse. *S* esposa.

Sterno, *I lay down:* strata, street, strath, stray, strew, prostrate, consternation.

Sto, *I stand:* stable, stage, stamina, stanza, state, station, statue, extant, distant, constant, substance, obstacle, destination. *F* état. *S* estado.

Stringo, *I draw tight:* string, stringent, strict, strait, strain, constraint, restrain, distrain, distress, district, boa-constrictor. *F* étroit. *I* stretto. *S* estrecho.

Struo, *I pile up:* structure, construct, destroy, construe, instruction. *F* construire. *I* costruire.

Super, *above:* superior, superintend, supreme, sum, summit, surface, surfeit, survive. *F* sur. *I* sopra. *S* sobre.

Surgo, *I rise:* surge, source, resurrection, resource, insurrection, insurgent.

Tango, *I touch:* tangent, tangible, tact, contact, contagious, contiguous, attain, intact, integral, integrity. *F* atteindre. *I* tatto, contatto.

Tego, *I cover:* tile, detective, protect, integument. *I* tegola (tile). *L* tectum (= roof). *S* teja.

Tempus, *time:* tense, temporal, contemporary, extemporary. *F* temps. *I* tempo. *S* tiempo.

Tendo, *I stretch:* tend, tense (= tight), tension, tentacle, tent, tentative, contend, intent, intend, intense, tempt, taunt, "tenter-hooks."

Teneo, *I hold:* tenable, tenacious, tenant, tenement, tenet, tenor, tenure, maintain, retain, retinue, continent, content, continuous. *F* tenir.

Tero, *I rub:* trite, triturate, tribulation, contrite, contrition, attrition. *I* tritico (corn).

Terra, *earth:* terra-cotta, terrace, terrestrial, terrier, territory, inter, Medi-terranean, tureen. *S* tierra.

Texo, *I weave:* text, texture, textile, context, pretext, tissue. *F* tisser. *I* tessere. *S* tejer.

Torqueo, *I twist:* torch, torment, torsion, tort, tortoise, tortuous, torture, contortion, retort. *F* tort (wrong). *I* torto. *S* torcer (to twist.)

Traho, *I draw:* trace, tract, trail, train, trait, treat, tare and "tret," attract, retreat, portrait.

Tres, *three:* trefoil, triangle, trident, trinity, trio, trivet, trivial. *F* trois. *I* tre. *S* tres.

Turba, *crowd:* turbid, turbine, turbulent, perturbation, disturb.

Unda, *wave:* undulate, Undine, abound, abundant, redound, inundate. *F* onde. *I* and *S* onda.

Unus, *one:* unit, unique, union, unicorn, uniform, universe, university, triune. *F* un. *I* uno.

Valeo, *I am strong:* valid, invalid, valerian, valiant, valour, value, avail, prevalent, convalescent. *F* valoir. *I* valetudine (health).

Veho, *I carry:* vex, veil, vein, vehicle, convey, convex, inveigh, invective, reveal. *F* voile, voiture (carriage). *I* vettura.

Venio, *I come:* venture, adventure, convene, convent, convention, supervene, prevent, revenue, avenue, convenient, covenant. *F* venir.

Verto, *I turn:* versatile, verse, vertebra, vortex, vertex, vertigo, convert, perverse, aversion, inversion, reversion, obverse, adverse, advertise, conversant, divorce.

Verus, *true:* very, verily, verity, verify, verdict, veracity, aver. *F* vrai. *I* vero. *S* verdad (truth).

Via, *road:* viaduct, devious, voyage, impervious, trivial, obvious, previous, obviate. *F* voie. *I* and *S* via.

Video, *I see*. viz. (short for "videlicet"), view, visage, vision, visible, visit, vista, provide, providence, prudence, revise, survey, envy, invidious, evident. *F* voir. *S* ver.

Vinco, *I conquer:* victor vanquish, convict, convince, evince, eviction, province (?). *F* vaincre. *S* vencer.

Vivo, *I live:* vivid, vivacious, vivisect, victuals, vital, revive, survival, convivial, viper (= vivipara, producing young alive). *F* vivre. *S* vivir.

Voco, *I call:* vocal, voice, vouch, vociferous, vocation, vocative, vocabulary, vowel, invoke, convocation. *F* invoquer.

Volvo, *I roll:* voluble, volume, revolve, convolution, involve, devolution.

Voveo, *I vow:* votive, votary, vote, devote, devout. *F* vouer. *I* votare.

Greek

In the process of anglicising a Greek word the following changes should be noted:

Greek υ (*u*) becomes English *y*, as συ τάξις, *suntaxis* (syntax).

Greek αι (*ai*) becomes English *æ*, as αἴσθησις, *aisthēsis* (æsthetic).

Greek οι (*oi*) becomes English *œ*, as οἶκος, *oikos* (œcumenical).

Greek γγ (*gg*), or γκ (*gk*), or γχ (*gch*), or γξ (*gx*) becomes English *ng, nk, nx,* as ἄγγελος, *aggelos.* (angel); ἄγκυρα, *agkura, ancura* (anchor).

[For the letters of the Greek alphabet and their English equivalents, see page 5374.]

Aēr (ἀήρ), *air:* aeronaut, aerolite. *F* aeronaute, aerolithe. *I* aeronauta, aerolito.

Agō (ἄγω), *I lead:* *E* pedagogue, synagogue, demagogue, strategy (stratos = army). *I* pedagogo, sinagoga, strategia. *S* estrategia.

AGŌN (ἀγών), *struggle :* agony, antagonist, protagonist, "Samson Agonistes" (Samson the struggler *or* wrestler). *F* agonie. *I* and *S* agonia.

AKROS (ἄκρος), *top, point :* acrobat (batos = walker, goer), acropolis, acrostic (stichos = a line). *I* acrobato, acrostico.

ALLOS (ἄλλος), *other :* allopathic, allotropy.

ANGELOS (ἄγγελος), *messenger :* angel, evangel. *F* ange, évangile. *I* angelo, evangelio.

ANTHRŌPOS (ἄνθρωπος), *man :* philanthropic, misanthrope, anthropology. *I* filantropico, misantropo, antropologia.

ARCHĒ (ἀρχή), *beginning, rule :* anarchy, archæology, archaic, monarch, archbishop, architect. *F* archevêque. *I* monarca, arcivescovo, architetto. *S* arzobispo, arquitecto.

ASTĒR (ἀστήρ), *star :* aster, asterisk, astronomy, astrology. *F* astérisque, astérie. *I* and *S* asterisco.

AUTOS (αὐτός), *self :* automobile, autobiography, autocar, autonomy, autocrat, authentic.

BALLŌ (βάλλω), *I throw :* parable, parabola, emblem, hyperbole, sym-bol, embolism. *I* iperbola, simbolo.

BAPTŌ (βάπτω), *I dip :* baptism, baptize. *F* baptême, baptiser. *I* battesimo, battezzare. *S* bautisme, bautizar.

BAROS (βαρος), *weight :* baritone, barometer, baroscope, isobar (isos = equal). *F* baromètre.

BIBLOS (βιβλός), *paper, book :* Bible, bibliography, bibliophile. *F* bibliothèque (library). *I* Bibbia, biblioteca (library).

BIOS (βίος), *life :* biology, biography, bioscope, microbe, amphibious. *F* amphibie. *I* and *S* anfibio.

CHOROS (χορός), *dance :* chorus, choir, chorister. *F* chœur, choriste. *I* and *S* coro, corista.

CHRONOS (χρόνος), *time :* chronology, chronometer, anachronism, chronic, chronicle. *I* cronologia, cronico, cronica.

CHRIŌ (χρίω), *I anoint :* Christ, Christian. *F* chrétien. *I* and *S* Cristo, cristiano.

CHRUSOS (χρυσός), *gold :* chrysalis, chrysoprase, chrysanthemum, chrysolite. *F* chrysalide. *I* crisalide.

DĒMOS (δῆμος), *people :* democracy, demos, demotic. *F* démocratie. *I* democrazia.

DOGMA (δόγμα), *opinion ;* DOXA (δόξα), *opinion, glory :* both from DOKEŌ (δοκέω), *I think :* dogma, orthodoxy, heterodoxy, doxology. *I* domma, ortodossia, eterodossia, dossologia.

DUNAMIS (δύναμις), *power :* dynamite, dynamics, dynasty

ĒLEKTRON (ἤλεκτρον), *amber :* electricity (because first observed in amber). *I* elettricita. *S* electricidad.

ERGON (ἔργον), *work :* energy, erg, metallurgy.

EU (εὖ), *well :* eucalyptus (*lit.* well-covered), euphemism, eucharist, euphony, eulogy, evangel. *F* eucharistie, évangile. *I* eucaristia, eufonia.

GASTĒR (γαστήρ), *stomach :* gastric, gastritis, gastronomy.

GĒ (γῆ), *earth :* geography, geology, apogee, giant (*lit.* earth-born). *F* géant. *I* and *S* gigante.

GENOS (γένος) *race, birth :* genealogy, oxygen, hydrogen (GENNAŌ, γεννάω, *I produce*), Genesis. *F* Genèse. *I* ossigeno, idrogeno, Genesi.

GIGNŌSKŌ (γιγνώσκω), *I know :* diagnosis, gnostic, a-gnostic, physiognomy (*cf.*, *L* cognosco).

GRAPHŌ (γράφω), *I write :* grammar, graphic, paragraph, telegram, epigram, graphite, graphoscope, cinematograph (*kinema* = movement). *F* grammaire. *I* grammatica. *S* gramatica.

HĒLIOS (ἥλιος), *sun :* heliotrope, heliograph, helium.

HEMI (ἡμι-), *half :* hemisphere, hemistich (*L* semi-). *I* emisfero.

HEPTA (ἑπτά), *seven :* heptarchy, heptagon. *I* ettarchia, ettagono. *S* heptarquia.

HETEROS (ἕτερος), *other :* heterodox, heteroclite, heterogeneous. *F* hétérogène. *I* eterogene.

HEX (ἕξ), *six :* hexameter, hexagon. *L* sex. *I* esagono. *S* exagono.

HIEROS (ἱερός), *sacred :* hieroglyphic, hierarchy. *I* geroglifo, gerarchia. *S* geroglifico, gerarquia.

HIPPOS (ἵππος), *horse :* hippodrome, hippopotamus (river-horse), Phil-ip (short for Philippos, *lover of horses*). *I* Filippo. *S* Felipe.

HOMOS (ὁμός), *same :* homogeneous, homologous. *F* homogène, homologue. *I* omogeneo, omologo.

HŌRA (ὥρα), *hour :* horology, horoscope. *F* horloge. *cf.* *L* hora. *I* orologio *S* reloj.

HUDŌR (ὕδωρ), *water :* hydrogen, hydrophobia, hydrostatics, hydraulic, dropsy. *F* hydropisie (dropsy). *I* idropisia (dropsy), idrofobia.

IDEIN (ἰδεῖν), *to see :* idea, idol, idyl, kaleidoscope. *F* idée, idole, idylle. *I* idea, idolo, idilio.

IDIOS (ἴδιος), *one's own*, or *peculiar :* idiot, idiom, idio-syncrasy (*idiot* originally meant *a private citizen*). *I* and *S* idiota, idioma.

KOSMOS (κόσμος), *order*, and so *the world* as opposed to chaos : cosmetic, cosmopolitan, microcosm.

KRINŌ (κρίνω), *I judge :* crisis, critic, hypocrite, hypercritical. *F* crise. *I* crisi *or* crise, ipocrita.

KRUPTŌ (κρύπτω), *I hide :* crypt, cryptogram, apo-crypha. *I* apocrifi.

KUKLOS, (κύκλος) *circle :* cycle, cyclometer, encyclopædia.

LAMBANŌ (λαμβάνω), *I take :* syl-lable, di-lemma, epi-lepsy. *F* syllabe. *I* sillaba, epilessia.

LEGŌ (λέγω), *I say, I choose :* lexicon, dialect, eclectic. *F* lexique. *I* lessico, dialetto. Also LOGOS (λόγος), *word :* logic, apology, geology, dialogue, syllogism, logarithm, tautology (tauto = the same).

LITHOS (λίθος), *stone :* lithography, monolith, lithia.

LUŌ (λύω), *I loosen :* para-lysis (palsy), analysis.

METRON (μέτρον), *measure :* metre, barometer, thermometer, metronome.

MĒTĒR (μήτηρ), *mother :* metropolis.

MIKROS (μικρός), *small :* microscope, microcosm, microbe (*lit.* small life): opposed to MAKROS, *large*, *e.g.*, macrocosm.

MISEŌ (μισέω), *I hate :* misanthrope, misogynist.

MONOS (μόνος), *alone, only :* monarch, monocle, monotony, monastery, minster, monotheism, monopoly [POLEŌ : I sell], monk. *F* moine (monk). *I* monaco (monk). *S* monje.

NAUS (ναῦς), *ship:* nautical, nautilus, nausea, aero-naut (nautes = a sailor).

NEKROS (νεκρός), *dead:* necropolis (a city of the dead, a cemetery), necromancy.

NOMOS (νόμος), *law:* astronomy, gastronomy, economy, Deuteronomy.

ONOMA (ὄνομα), *name:* syn-onymous, patronymic, onomatopœic, anonymous, pseudonym.

OPSIS (ὄψις), *sight:* optic, synopsis. *I* ottica.

ORTHOS (ὀρθός), *straight, right:* orthodox, orthography.

OXUS (ὀξύς), *sharp:* oxygen, oxytone, paroxysm. *I* ossigeno, parossismo.

PAIS (παῖς), *boy:* pedagogue; PAIDEIA, *instruction:* encyclopædia.

PAN (πᾶν), *all:* panto-mime, pantheist, panegyric, panacea, pandemonium, panorama. (*Panic* takes its name from the god Pan, who used to inspire terror.)

PATHOS (πάθος), *suffering:* pathos, pathetic, sympathy, apathy.

PENTE (πέντε), *five:* pentagon, pentateuch (teuchos = book), pentameter, pentecost (*fiftieth*). *F* pentecôte.

PEPŌ (πέπω), *I digest:* pepsine, peptonise, dys-peptic, "Peps."

PHAINŌ (φαίνω), *I show:* phenomenon, sycophant ("fig-shower"), phantasm, phantom, phase, emphasis. *F* fantaisie, fantôme. *I* enfasi (emphasis).

PHARMAKON (φάρμακον), *drug:* pharmacy, pharmaceutical, pharmacopœia. *I* farmaco (remedy).

PHĒMI (φημί), *I say:* blasphemy, blame, prophesy, aphasia (loss of speech). *I* bestemmia, biasimo.

PHERŌ (φέρω), *I bear:* phos-phorus (*lit.* light-bearer), metaphor (*cf.*, *L* fero = *I bear*).

PHILOS (φίλος), *fond of:* philosophy (sophia = wisdom), philanthropy, Philadelphia, Philip, philtre, biblio-phile.

PHŌNĒ (φωνή), *voice:* phonetic, telephone, phonograph, microphone, anthem (= anti, *against*, phonē, *voice*). *I* and *S* antifona.

PHŌS (φώς), *light:* phosphorus, photography, photophobia (dread of light).

PHRAZŌ (φράζω), *I speak:* phrase, paraphrase, periphrasis, phraseology. *I* and *S* frase.

PHRĒN (φρήν), *mind:* phrenology, frenzy, frantic. *F* frénésie, frénétique. *I* frenesia, frenetico.

PHTHIŌ (φθίω), *I waste away:* phthisis. *I* tisi *or* tisichezza (consumption). *S* tisis.

PHUSIS (φύσις), *nature:* (from PHUŌ, φύω, *I beget*): physics, metaphysics, physiology, physician, physiognomy.

PLANAŌ (πλανάω), *I cause to wander:* planet, aero-plane. *I* pianeta.

PNEUMA (πνεῦμα), *air, wind:* pneumatic, pneumonia. Greek for (Holy) *Spirit.* *S* neumatico.

POIEŌ (ποιέω), *I make:* poet, poem, poesy, pharmacopœia, onomatopœic.

POLIS (πόλις), *city:* policy, politics, metropolis, acropolis, cosmopolitan, police, Neapolis (Naples), Napoleon. *I* polizza (policy), polizia (police).

POLUS (πολύς), *many:* polyanthus, polygamy, polygon, polytechnic, polytheism, polypus.

POUS (πούς), *foot:* podagra (gout), tripod, trapeze, antipodes. *F* podagre.

PRESBUS (πρέσβυς), *old man:* presbyter, priest, Presbyterian. *F* prêtre. *I* prete. *S* presbitero.

PRŌTOS (πρῶτος), *first:* protagonist, protein, "protose," protocol, protoplasm, prototype.

PSALLŌ (ψάλλω), *I play the lyre:* psalm, psalter. *F* psaume, psautier. *I* and *S* salmo, salmista.

PSEUDĒS (ψευδής), *false:* all words beginning with *pseudo*, as pseudonym, pseudo Christian.

PSUCHĒ (ψυχή), *soul:* psychology, psychic (connected with PSYCHEŌ, *I breathe*). *I* psicologia. *S* psicologia.

PTŌMA (πτῶμα), *a fall*, (from PIPTO, *I fall*): ptomaine, ptosis, sym-ptom. *I* sintomo.

PUR (πῦρ), *fire:* pyramid, pyre, pyrites, pyrotechnics, empyrean. *F* empyrée.

RHĒGNUMI (ῥήγνυμι), *I break:* cataract, hæmorrhage. *I* cateratte. *S* catarata.

RHEŌ (ῥέω), *I flow:* rheum, rheumatism, catarrh, rhythm. *I* and *S* ritmo.

SCHOLĒ (σχολή), *leisure:* school, scholar. F école, écolier. *I* scuola, scolare. *S* escuela.

SKOPEŌ (σκοπέω), *I look, I view:* scope, bioscope, microscope, telescope, episcopal, bishop, sceptic. *F* évêque. *I* vescovo (bishop). *S* obispo.

STASIS (στάσις), *standing* (from HISTEMI, ἵστημι, *I make to stand*): ecstasy, apostasy, system, statics. *I* estasi.

STELLŌ (στέλλω), *I send:* epistle, apostle. *F* épître, apôtre. *I* epistola, apostolo.

STEREOS (στερεός), *solid:* stereoscope, stereotype.

STREPHŌ (στρέφω), *I turn:* catastrophe, apostrophe, strophe, antistrophe.

TAPHOS (τάφος), *tomb:* epitaph, cenotaph.

TAXIS (τάξις), *arrangement* (from TASSO, τάσσω, *I arrange*): taxidermist, syntax. *I* sintassi.

TEINŌ (τείνω), *I stretch:* tone, tonic, monotony, baritone, hypotenuse, protasis.

TĒLE (τῆλε), *afar:* telephone, telegraph, telepathy, telescope.

TEMNŌ (τέμνω), *I cut:* a-tom, epi-tome, tome, anatomy.

THEOS (θεός), *god:* theology, theosophy, theism, theocracy, apotheosis, enthusiasm(?) (*cf.*, *L* deus). *I* and *S* teologia.

THERMOS (θερμός), *heat:* thermometer, thermal, isotherm.

TITHĒMI (τίθημι), *I place:* thesis, hypothesis, antithesis, synthesis, theme, epithet, anathema, apothecary, hypothecate (THĒKĒ, θήκη = box).

TOPOS (τόπος), *place:* topic, topical, topographer.

TREPŌ (τρέπω), *I turn:* tropic, trophy. *I* and *S* trofeo.

ZAŌ (ζάω), *I live:* ZŌON (ζῶον), *animal:* zoology, zoo, zodiac.

LANGUAGES *concluded*

GAS MANUFACTURE

Illuminating and Fuel Gases. The Processes Followed and the Appliances Used in their Manufacture, Purification, and Distribution

WHEN Van Helmont, in the sixteenth century, invented the word *gas* he applied it to an occult principle which he supposed to pervade all matter. Modern chemistry applies the word to matter in an aeriform condition at ordinary temperatures. In a popular sense the word gas is used to describe the inflammable gaseous matter which is obtained by distilling coal, and it is better defined by adding words indicating the source as "coal-gas." The various gases have been dealt with in the section devoted to Chemistry, from which it has been gathered that many elements are in the gaseous condition. Illuminating and heating gas is a mixture of two or more elemental gases, such as hydrogen, nitrogen, oxygen, carbon monoxide, methane, and ethylene. Some gases are combustible, and are obviously of most use for illuminating and heating purposes, but certain non-combustible gases are unavoidably present as diluents which have no heating value.

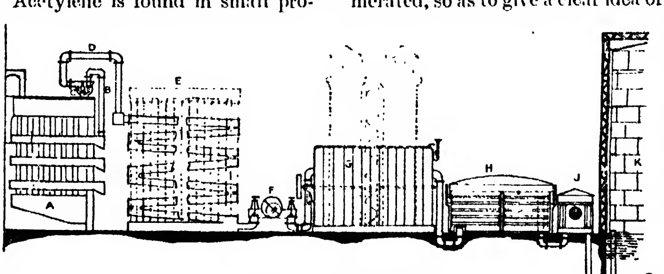
The chief gases which are present in either illuminating or heating gas are the following, which for convenience are divided into two classes.

Combustible Gases. The letters which follow the names are the chemical symbols. Hydrogen (H), carbon monoxide (CO), marsh gas (CH_4), ethylene (C_2H_4), acetylene (C_2H_2), benzene vapour (C_6H_6), naphthalene vapour ($C_{10}H_8$). The first two, hydrogen and carbon monoxide, are of the greatest importance, and occur in the largest proportions in gas. Marsh gas is also known as methyl hydride and methane, while mixed with air in explosive proportions it forms the dreaded *fire-damp* of the coal-miner. Although only marsh gas is here mentioned, it must be taken to be only the most important of what is known as the methane series of hydrocarbons, which always results when a body like coal is submitted to great heat. Marsh gas is not present in large quantities in coal-gas, but as it contributes to the luminous properties, it is of considerable importance. Natural gas, which will be referred to presently, is largely marsh gas. Ethylene, known also as olefiant gas, ethene, or heavy carburetted hydrogen is the most important of the ethylene series of hydrocarbons, which, like the methane series, consists of many gases of like chemical constitution. Acetylene is found in small proportions in coal-gas but larger quantities are made from calcium carbide, and so easily and cheaply, that this gas is burnt alone as an illuminating gas. The method of preparation will be separately dealt with. Benzene and naphthalene, it will be noticed, are referred to as *vapours*, because substances which are not gaseous at ordinary temperatures are not spoken of as gases. Benzene is a liquid and naphthalene a solid when isolated from gas, but they exist in gas in a dissolved state. They are important constituents, as they play a considerable part in the luminosity of gas. Naphthalene is apt to deposit from gas in very cold weather, and is the substance which chokes up the gaspipes in winter, causing much trouble by diminishing the supply.

Incombustible Gases. These, as has been explained, are diluents in gas, and are accidentally present, owing to the manner of preparation. The chief diluents are nitrogen, carbon dioxide, oxygen, and water vapour. Of these, nitrogen is present in the greatest proportion. It is an inert gas, and is the chief constituent of the atmosphere, but not the most important. Carbon dioxide is the gas used in aerating table waters. Most of this gas is taken out of coal-gas by a chemical process, but it is never entirely eliminated. Oxygen is known as a supporter of combustion—that is, gas needs oxygen (from the air) before it will burn. The oxygen found in coal-gas in small quantities comes from air that has obtained access at some stage of the process.

Luminosity. The greater part of the gases enumerated in the preceding paragraph on combustible gases do not give light when burnt. Hydrogen and carbon monoxide give only a blue flame when burnt, the luminous properties of gas being due to the hydrocarbons present—methane, ethylene, acetylene, benzene, and naphthalene. When the gas is required for heating purposes only it is not necessary to ensure the presence of hydrocarbons, and, as will be presently shown, the gases used for fuel purposes burn with a blue, non-luminous flame. In speaking of a blue flame, it should be noted that the non-luminous flame produced from coal-gas as burnt in domestic gas-ovens is due to the admixture of air near the burners. This results in the more nearly perfect combustion of the gas and loss of luminosity.

Various Kinds of Gases. Coal-gas, although the most familiar gas, is by no means the only gas used for illuminating and heating purposes. The chief kinds will now be briefly enumerated, so as to give a clear idea of what the various gases are, especially as some of the gases have several names. Each gas will be dealt with in its turn in succeeding parts of this article. *Coal-gas* is obtained by strongly heating coal in a closed fire-clay retort, but similarly *wood-gas* and *peat-*



1. SCHEME OF GAS MAKING

A. Furnace with retorts B. Ascension pipe C. Foul main D. Pipe leading to condenser E. Condensers (dotted lines showing vertical form) F. Exhauster G. Washer (dotted lines at back showing the tower form of washer) H. Purifier J. Station meter K. Gasholder

gas are made by heating wood and peat. *Natural gas* is found in various parts of the earth, and has merely to be collected and distributed through pipes to the house or factory. *Oil-gas* is made by decomposing petroleum or shale oil by heat, *oxy oil gas* being a variety obtained by mixing oil gas and oxygen. *Water gas* is made by passing steam over red-hot coke, the water vapour being split up into its elemental constituents. This gas is also known as *blue gas*. When mixed with hydrocarbon vapours, so as to make it burn with a luminous flame, water gas is known as *carburetted water gas*. Then there is the important class of gases known as *producer gas, generator gas, Siemens gas, Dowson gas, gaz pauvre (poor gas)*, or *mixed gas*. These being often a mixture of water gas and coal gas, as in the Dowson gas, are often referred to as *semi-water gas* or *steam enriched gas*. *Mond gas* is produced for fuel purposes by the combustion of small coal or slack, and the gases evolved from the blast furnaces or coke ovens of iron and steel foundries are known as *blast furnace gas* or *coke-oven gas*, according to the source.

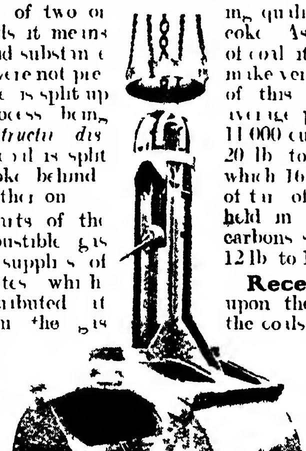
When producer gas is used in a suction producer—an apparatus making fuel gas for direct consumption in a gas engine—the term *suction gas* is sometimes used. *Methane hydrogen gas* is a gas made from steam and tar, being thus really a variety of carburetted water gas. *Air gas* or *gazolene gas* is simply air mixed with hydrocarbon vapour, the hydrocarbon used being gasolene or some similar light distillate of paraffin.

Distilling. As the word *distil* has been used and will be used again in this article, it is well that its meaning should be understood. Distilling, as applied, for instance, to the preparation of alcohol, implies that by means of heat one liquid is separated from a mixture of two or more liquids. In the case of solids it means the splitting up of a complex solid substance by heat into other matters which were not previously present. Coal, for instance, is split up or decomposed by heat, the process being more correctly referred to as *destructive distillation*. Roughly speaking, the coal is split up, giving off gas and leaving coke behind, but this will be fully explained further on.

Natural Gas. In many parts of the world Nature supplies a combustible gas ready made. There are large supplies of natural gas in the United States which, when collected, have been distributed at Pittsburg a hundred miles from the gas well at 5d. per 1,000 cubic ft. Unfortunately, the supplies of natural gas give out in time, with the consequence that industries which have flourished because of the supply of cheap natural gas have declined and caused ruin to towns in the United States which depended on the maintenance of manufacturing industries. A supply was discovered at Heathfield in Sussex, in 1897, by the London Brighton, and South Coast Railway Company, in searching for an underground water supply, and this has since been utilised for fuel and lighting purposes. Natural gas generally smells of paraffin, and consists chiefly of methane, with small quantities of other hydrocarbons, oxygen, hydrogen, and carbon monoxide. The proportion of methane in the Heathfield supply is less than is found in many natural gases from American sources, but the amount of higher hydrocarbons is greater, with the result that the English gas is more luminous.

Coal-gas. Coal is placed in long fireclay tubes known as *retorts*. The retorts are closed at both ends, but near one end there is a pipe through which the gaseous products are conveyed. The retorts are subjected to great heat by a furnace underneath, and give off crude gas. The gas is then cooled or condensed, when tar separates, the gas passing on to scrubbers or washers to be deprived of the last portions of tar and the ammonia which the gas contains. From the scrubbers the gas passes to purifiers to remove the remaining gaseous impurities, such as carbon dioxide, carbon bisulphide, sulphuretted hydrogen, and cyanogen, and is then placed in the gasholders from which it is distributed through the gas mains and pipes to the place where it is used. The process may be followed by referring to the diagram [1].

Varieties of Coal. The gasmaker recognises two kinds of coal—cannel, candle, or parrot coal and common or gas coal. Cannel coal gives a gas containing a large proportion of ethylene, the constituent which contributes most to the luminosity of the gas. Common or gas coal may be divided into caking and non-caking coal. Caking coal softens when heated and after the volatile constituents have been expelled yields a coke which is of cellular structure but which does not show the original shape of the coal. The non-caking coal retains the form of the coal in the coke and does not soften before giving up its gaseous constituents. Anthracite coal finds a special use in the production of fuel gas. It should be especially noted that not only does the gasmaker have to judge coal by the gas yield but he has to take into account the illuminating quality of the gas and the texture of the coke. As to the yield of products from a ton of coal it will be seen that it is not possible to make very definite statements. For the purpose of this paper it may be taken that the average products comprise 10,000 cubic ft. to 11,000 cubic ft. of gas, holding in suspension 20 lb. to 24 lb. of hydrocarbon vapours, of which 16 lb. to 18 lb. are benzene, and 120 lb. of tar, of which 25 lb. to 30 lb. are carbon held in suspension, 2 lb. to 3 lb. are hydrocarbons similar to the vapours in the gas, and 12 lb. to 14 lb. are naphthalene.



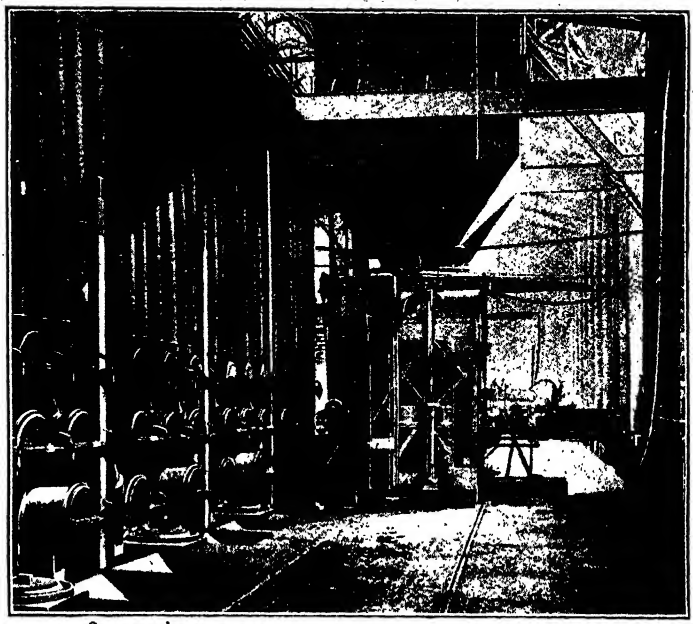
2. HONE'S PATENT GRAB
(Thames Ironworks Co. Ltd.)

Receiving the Coal. It depends upon the site of the gasworks as to how the coals are taken in. If the coal arrives by water it is, in modern works, taken from the ships or barges by self-acting grabs, such as Hone's patent grab [2], and delivered to elevating and conveying plant to the stores or retort houses. If the coal arrives by railway, mechanical appliances are employed for emptying the waggons, which, by means of an inclined railway, have been taken up to an elevated position. Where conveyors are used the larger lumps of coal will need breaking before being handled by the elevator buckets, there being two kinds of breakers—the roller and jaw types. If needed the coal can be automatically weighed at this stage.

Retort Houses. The plan of the building in which the coal is going to be distilled depends upon the particular system that is to be employed. The building is constructed of steel framework and

brick, the circular girder roof being largely adopted for double-bench retort houses. The working floor level is known as the *stage*, and below the level is the furnace and also the arrangements for conveying away the coke that comes from the retorts.

Retorts. Coal is distilled in fireclay retorts, which, in Great Britain, are machine made. The retorts are of two lengths, and are known as *singles* or *doubles*. The single retorts are from 8 ft. to 10 ft. long, and of D-shaped section, the height being 12 in. to 16 in. Double retorts are 20 ft. long, and are really two retorts set back to back, with a lid on each end. In the case of single retorts, one end only is fitted with a mouthpiece, the other end being built up. The end of the retort has fitted on it an iron socket to receive the lower end of the ascension pipe, or upright pipe which leads the gas from the retort, and a lid or mouthpiece. The type known as Morton's self-sealing mouthpiece is much used, but Candler's and Balfour's are varieties which more readily permit of the renewal of the wearing parts. The retorts are set in beds of from three to twelve, and are, from their position, known as bottoms, middles and tops. The collection of retorts, as seen in 3, is called a *bench*.



3. WEST'S COMBINED CHARGING AND DRAWING MACHINE
(West's Gas Improvement Co., Ltd.)

The Furnaces. These retorts are supported on fireclay walls 2ft. apart, which act as flues for the heat of the furnace. Originally, the retorts were heated direct by coke, but Sir William Siemens' regenerate furnace, or some similar type, is generally used at the present time. In this kind of furnace, highly-heated gas is made to impinge on the outer surface of the retorts, the heating value being increased in some types by the injection of steam, which forms a proportion of water-gas. This type of furnace will be referred to when we deal with producer-gas.

Charging and Drawing. Single retorts have a capacity of from $1\frac{1}{4}$ cwt. to 3 cwt. of coal, double retorts taking a correspondingly larger charge. The charging of the retorts is done by one of four methods: (1) hand shovelling; (2) the use of a long scoop; (3) by machinery; or (4) by gravity. The last-named method will be dealt with in our consideration of inclined retorts. By whichever of the three methods employed, the object in view is to spread the coal evenly on the floor of the retort. The shovel method is obviously the slowest, and necessitates much loss of heat. It is also terrible work for the stoker. When a scoop carrying the whole charge is employed, the time taken to charge a retort is under a minute. The scoop of coal is introduced into the retort and then turned over and withdrawn.

Charging Machinery. Much saving of labour results when machinery is employed for charging retorts, especially where power is used to drive the machines. West's manual charging machine is a simple type from which the well-known West's machines were evolved. The modern types of West's charging machines are driven by compressed air and run on rails on the stage in front of the retort bench. The retorts on one level are charged at the same time, after which the machine is adjusted for other levels. A scoop carrying the charge of coal is introduced into the retort, reversed, but each retort takes two scoopfuls. The first time the scoop enters the retort it turns over on the right, and the second time on the left side. The four levers for controlling the various actions of the machine are placed within easy reach of the stoker.

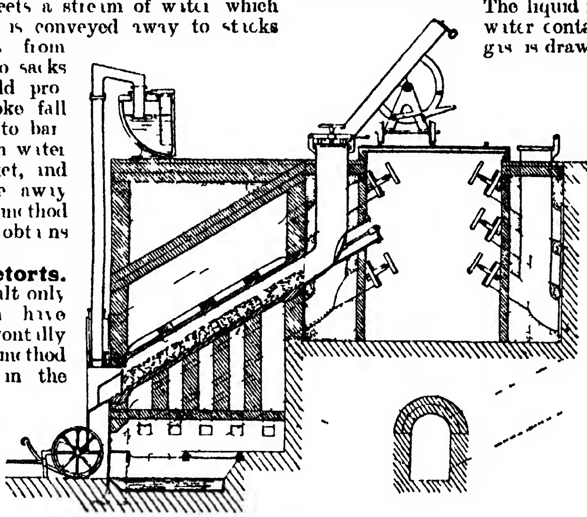
The Arrol-Foulis Machine. Another well-known type of charging machine is the one devised by Sir William Arrol and Mr. William Foulis. It is worked by hydraulic power at a pressure of 400 lb. per square inch. In this machine a hydraulic ram pushes charges of coal into the retort, five or six strokes being needed to charge a 10 ft. retort with $3\frac{1}{2}$ cwt. of coal.

Other Charging Machines. For small works the rapid charging machine of Messrs. Biggs, Wall & Co. is much used. There are two, one worked by manual labour and the other by power in the form of a small gas-engine. In Ruscoe's charging machine the charge is put into the retort in one operation by means of two scoops side by side, these being overturned in opposite directions. The newest types of charging machine, such as the De Brouwer and the turbine machine, are driven by electricity; in the latter machine the coal is shot into the retort by centrifugal force.

Drawing Machines. Sometimes combined in the same machine as the charging machine is a device for raking out the coke when it has been exhausted of its gas, or this may be a separate drawing machine [3]. The makers whose names have been mentioned in connection with charging machines also manufacture the drawing machines.

These consist essentially of a rake which is introduced into the retort and pulls out the glowing coke Water cooling devices are employed to cool the rake rod. The coke is allowed to fall down a space beneath the stage, being directed by means of an iron screen or *fender* placed in front of the drawing machine, and is taken away by *conveyors*, consisting of grids, or plates running on chains While on its journey the coke meets a stream of water which quenches it and it is conveyed away to stacks or storage hoppers from which it is filled into sacks or waggons The old process is to let the coke fall from the retort into barrows, quench it with water from a hose or bucket, and then wheel the coke away to the yard This method is costly, but still obtains in small gasworks

Inclined Retorts. So far, we have dealt only with retorts which have been placed horizontally in the setting This method is being replaced in the newer gasworks by an improvement which consists in setting the retorts at an angle [4] The method is due to André Coze, of Rheims, who patented the improvement in 1885 The retort are set at an angle of 29 to 34, and are fed at the uppermost end by travelling shoots thus saving time and expense of hand or machine stoking The coal storage tanks are placed above the level of the shoots leading to the retort, and by means of levers, measured quantities of coal are let fall into the retorts The lower end of the retort is fitted with the usual self sealing lid from which the ascension pipe rises When the coal enters the retort it is met at the lower end by a check plate against which it forms itself into a regular layer along the bottom of the retort When the distillation is finished the lids on the lower ends or drawing stage are opened and the coke falls out automatically or with slight assistance The latest development is to employ retorts set vertically, the claim being that a superior yield of gas and better quality of coke are obtained



4 INCLINED RETORTS

Effect of Temperature. The retorts are heated to a temperature of from 1 800 F to 2 000 F that being the end temperature four or six hours after charging the retort, when the coke is ready for drawing The effect of heating coal at the higher temperature is partly to decompose some of the tar and increase the quantity of ammonia in the crude gas The impurities, carbonic acid, cyanogen and the sulphur compounds are also increased Put in another way, this means that the higher temperature produces a larger yield of gas, but the illuminating effect of the gas is lower It takes from 15 tons to 20 tons of coke to distil 100 tons of coal, the lower amount being required in the regenerative furnaces, but as little as 10 tons of coke are needed in some of the modern generator furnaces

The Hydraulic Main. It will be remembered that each mouthpiece of the retorts is fitted with an ascension pipe, an upright pipe which conveys the gas from the retort to what is called the *hydraulic main.* The ascension pipes are about 5 in in diameter, and rise some distance above the retort bench; they join a descending pipe by means of a short bridge of horizontal pipe, the dip pipe leading to the hydraulic main This pipe dips about 1 in below the water in the main The hydraulic main is usually square, or with a rounded bottom, and is built up in sections The liquid it contains is tar and water containing ammonia. The gas is drawn through this main by pumping engines or exhausters [5], to be referred to presently The purpose of the liquid is to condense much of the tar and like matters carried over by the hot gas, and prevent the gas returning to the retort when it is opened for charging All the retorts in one retort house are connected with the same hydraulic main The pipe which conducts the gas and liquid from the hydraulic main is known as the *foul main* This is connected with the *tar well* the tar and aqueous part separating in time while the gas goes on to a series of cooling pipes known as the *condenser*

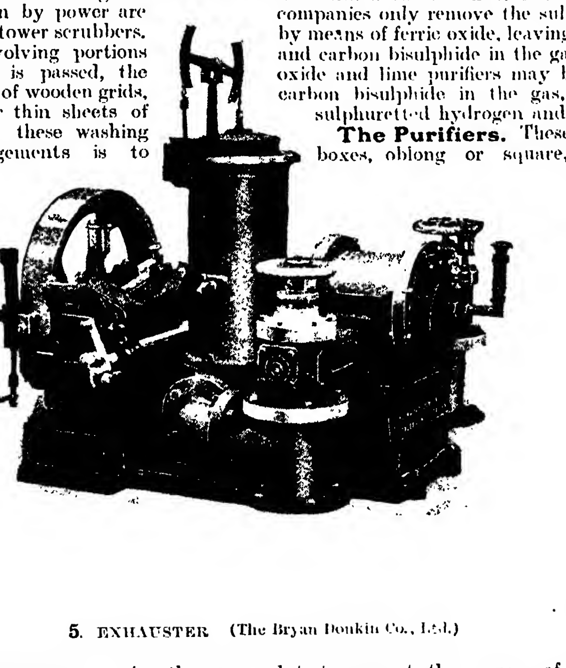
Composition of Crude Gas. This is a convenient place to refer to the composition of the crude gas as it comes from the retorts The combustible gases contained in the crude gas are hydrogen (42 per cent to 53 per cent), methane (32 per cent to 39 per cent) carbon monoxide (3 per cent to 10 per cent) gaseous hydrocarbon (2 5 per cent to 4 5 per cent) The impurities which it is desirable to remove as far as possible are small percentages of carbon dioxide nitrogen sulphuretted hydrogen ammonia cyanogen and carbon bisulphide The nitrogen is not removed by any of the subsequent purification processes

The Condenser The gas, after it leaves the hydraulic main passes through a series of vertical or horizontal cast iron pipes so arranged that the gas has to traverse the whole length of the pipe During its passage in this condensing apparatus the gas is cooled and reduced in volume, and there is separated more tar and aqueous matter, which is led off to the tar well before referred to by syphon arrangement Climatic conditions in England render air cooled condensers efficient although in hot weather it is necessary to spray the outside of the tubes with water The condensing pipes are from 6 in to 12 in in diameter, and there are from nine to twelve rows of pipes placed above each other (in the modern horizontal condensers) Other kinds of condensers are cooled by water the principle being that the gas passes up a tower within which are vertical pipes with water circulating therein. Clapham's "Eclipse" condenser has sometimes as much as a mile and a half of tube in one condenser.

The Exhauster. The gas passes from the condenser to the exhausters [5]. These are cylindrical pumps, the purpose of which is to draw the crude gas away from the retorts, and, when the gas has passed through the exhausters, to force it onwards through the washing and purifying apparatus. The exhausters generally used are Beale's, invented in 1848, and improved in 1866 and 1871. Since then E. B. Donkin has patented a further advance in this type of rotary exhauster by which the internal drum is made to do duty as a piston. The exhausters are driven by a steam-engine, the rate being carefully regulated so as to maintain the vacuum in the hydraulic main at a constant pressure.

Scrubbers and Washers. From the exhausters the gas passes to the scrubbers or washers, where it is deprived of its ammonia and a part of the carbonic dioxide, sulphuretted hydrogen, and cyanogen. There are different types of scrubbers, the principle of all being that the gas is finely broken up and brought into contact with a stream of water passing the opposite way to the gas. The tower form of scrubber consists of a tall tower filled with coke or wooden grids, a stream of water falling from the top of the tower through the coke. The gas enters at the bottom, and has to make its way up through the wet coke, losing on its way the ammonia it contains. The towers are run in series, the first one containing gas liquor, and the last one clean water. As the liquors become saturated they are passed to a plant for recovering the ammonia. Washer scrubbers driven by power are now replacing the older tower scrubbers. These have central revolving portions through which the gas is passed, the interior consisting either of wooden grids, brushes, wooden balls, or thin sheets of metal. The aim in all these washing and scrubbing arrangements is to saturate the liquors fully, using as little water as possible, because it is a needless expense to have to recover ammonia from weak solutions.

Tar Extractors. Means are adopted at various stages of the process of condensing and washing to lead off the tar, but a miniature scrubbing apparatus placed before the scrubbers proper, with the idea of preventing clogging of the scrubber, is known as a *tar-extractor*.



5. EXHAUSTER (The Bryan Donkin Co., Ltd.)

Chemical Purification. As the gas leaves the scrubbers it still contains sulphuretted hydrogen (1 per cent. to 2 per cent.), carbonic acid (1 per cent. to 3 per cent.), and small quantities of carbon bisulphide, and other sulphur compounds. The removal of these impurities is a chemical process.

It is provided by the Gasworks Clauses Act of 1847, that gas shall not give evidence of the presence of sulphuretted hydrogen when tested with lead-paper. This and other sulphur compounds are objectionable in gas, because the products of combustion which they yield (sulphur dioxide) are of an injurious character, both when breathed and because of their action on the contents of a room. Carbon dioxide diminishes the luminosity of the gas, and, as has been explained earlier in this article, it is not a combustible gas. The obligations of the various gas companies in regard to the removal of impurities are not identical. In some cases the carbon dioxide need not be removed, but as it diminishes the luminosity of the gas it is to the gas company's interests to see that it is removed entirely or diminished very considerably.

Scheme of Purification. To remove carbon dioxide the gas is passed over lime, the sulphuretted hydrogen is removed by ferric oxide or Weldon mud, and the carbon bisulphide by sulphided lime. The order of removal differs, as also does the number of purifiers which are devoted to chemical purification. This, as has been explained, is because of the differences in the legal requirements of the gas undertakings. If a complete scheme be adopted, it will require eight purifiers, the first two being lime vessels, the next two ferric oxide containers, two more for sulphided lime, and the last two in the nature of check vessels (often containing Weldon mud), to remove the last traces of sulphuretted hydrogen. Another scheme, known as the *all-lime* system, requires four purifiers containing lime and a check-box of ferric oxide. Other gas companies only remove the sulphuretted hydrogen by means of ferric oxide, leaving the carbon dioxide and carbon bisulphide in the gas, and, again, ferric oxide and lime purifiers may be used, leaving the carbon bisulphide in the gas, but removing the sulphuretted hydrogen and carbon dioxide.

The Purifiers. These are large cast-iron boxes, oblong or square, each vessel being from 30 ft. to 40 ft. square. Inside, a series of wooden grids is arranged, and carries the purifying material. These shelves are arranged so that the gas passes over as much of the purifier as possible—that is, the journey taken by the gas from its entrance to its exit is as long as possible. The lid of the purifier has a flange, which dips into a channel or U-section round the top of the purifier containing water, thus acting as a seal or lute to prevent the escape of the gas. Dry seal covers are used in modern works. The lid is brought into contact with strips of indiarubber, and fastened down with swing bolts. The number of tiers of grids varies according to the material and depth of the purifier: the latter is generally 5 ft. The set of purifiers is arranged with valves and exit pipes so that the order of the purifiers can be changed or put out of action to permit of recharging. It is usual to have more purifiers than are

required for use, so that the process is efficiently carried out. When it is found that a purifier is not working properly, it is put out of action and a fresh purifier is used in its place.

Lime Purifiers. Lime, when freshly slaked, is one of the best substances known for absorbing carbon dioxide, the substance formed being a carbonate. The lime purifiers have generally four tiers of grids, upon which the lime is placed about 4 in. deep. The lime is carried alongside the purifier in wheelbarrows, and arranged by a workman with a shovel. The removal is effected by means of an outlet provided at the bottom, or the spent lime is shovelled into sacks and lifted out. The lime, as it is obtained from the earth, is burnt and slaked by watering it. A cubic yard of good burnt lime requires about 135 gal. of water to slake it, yielding 2¼ yd. of slaked lime. It takes 5·7 cubic yd. of slaked lime to purify 1,000,000 cubic ft. of gas from carbon dioxide, this being the quantity needed in practice; in theory, it is less. In addition to taking out the carbon dioxide the lime also takes out a portion of the sulphur (8 gr. to 10 gr. from 100 cubic ft. of gas), as carbon bisulphide, as well as some of the sulphuretted hydrogen and cyanogen.

Oxide Purifiers. The purifiers which serve for the removal of sulphuretted hydrogen are filled either with hydrated ferric oxide or a mixture of the oxide and Weldon mud (chiefly manganese dioxide). The ferric oxide that is used is natural bog ore (known also as *iron sponge*, or *iron mass*), which occurs in extensive deposits in the North of Ireland and Holland. This bog ore contains about 30 per cent. of ferric oxide, the rest of the substance being moisture and vegetable fibre, both of which are useful in dividing it, so that the sulphuretted hydrogen has a better chance of being absorbed. About 6 yd. of bog ore will be needed in practice to purify 1,000,000 cubic ft. of gas from sulphuretted hydrogen. The bog ore, which is reddish-brown, turns black when it has absorbed sulphuretted hydrogen, the ferric oxide being converted into ferric sulphide.

Revivification. The ferric sulphide which is obtained by passing sulphuretted hydrogen over ferric oxide is a very unstable body. It has the curious property, when exposed to the air, of absorbing oxygen and returning to its original state as ferric oxide, the sulphide being left as free sulphur, mixed with the ferric oxide. This property is made use of for restoring the ferric oxide to efficiency when it has become saturated with sulphuretted hydrogen, the process being known as *revivification*. The material can be revivified as many as fourteen times, after which the free sulphur it contains (about 50 per cent.) so dilutes the compound as to render it useless. This sulphur is either recovered at the gasworks or the sulphur-laden oxide is sold to makers of sulphuric acid. The revivification is attended by changes of colour which enable the workman to tell how the change is progressing. Sometimes the absorption of oxygen is so rapid that the mass takes fire, so it has to be carefully watched, and not spread out in layers of less than 12 in. deep. The oxide is taken out of the purifiers for revivification, and spread on a concrete floor, being turned over every few days until the oxidation is complete. A process of revivification in the purifiers is practised at some works, gas mixed with air or oxygen being passed through. This obviously saves a lot of handling of the oxide, but is not so easily managed, and the ferric oxide in the purifier has a tendency to become caked when it does not readily absorb sulphuretted hydrogen.

Weldon Mud. The use of Weldon mud in place of bog ore was proposed by Messrs. Hood and Salamon in 1888. Weldon mud is a by-product in the manufacture of chlorine, and a nuisance to the alkali-maker. Hood and Salamon, by a process of decantation, washed out most of the calcic chloride contained in the mud, leaving a mixture of hydrated oxides of lime and manganese. The mass is allowed to dry until it is in a moist, crumbly condition, when it is ready for use in the purifier. The manganese oxide becomes manganese sulphide by the absorption of sulphuretted hydrogen, changing its colour from yellowish-brown to pink. When saturated with sulphuretted hydrogen, the Weldon mud is revivified in like manner to bog ore. It is claimed to be superior to bog ore, because of the greater activity of Weldon mud.

Carbon Bisulphide. There still remains a very objectionable impurity in the gas—carbon bisulphide. The process of removal is to pass the gas over lime that has been saturated with sulphuretted hydrogen. This is prepared by passing gas free from carbon dioxide, but still containing sulphuretted hydrogen, through a lime purifier, forming sulphides of lime. This acts upon the carbon bisulphide in the gas, and forms probably calcium thiocarbonate. Before passing the gas through the sulphide purifiers it contained from 30 gr. to 40 gr. of carbon bisulphide per 100 cubic ft. of gas, but this is reduced by passage through the purifiers to as low as 6 gr. of sulphur compounds. In London the maximum of sulphur that is allowed in the gas is from 17 gr. to 22 gr. per 100 cubic ft., according to the season. As a matter of fact, the quantity present is much below the maximum—some 10 gr. to 12 gr. A purifier of about 28 ft. by 36 ft., charged with six 10-in. tiers of lime, will take up about 5 tons of sulphuretted hydrogen, and will absorb, when in action, at least 3 tons of carbon bisulphide. Two such vessels should suffice for a year's working on a daily output of about 3,000,000 cubic ft. of gas.

Cyanogen. The cyanogen compounds which are present in the gas, chiefly combined with ammonia, are taken out by several stages of the purification processes. The water in the scrubbers absorbs some, the lime another portion, and the ferric oxide the remainder. When absorbed by lime, it is difficult to recover the cyanogen in a paying form, but it is easier to obtain it when it has been absorbed by ferric oxide. For this reason, when cyanogen recovery is practised, lime purifiers must not be placed before oxide purifiers. Special processes are being worked for the recovery of cyanogen compounds, these latter being absorbed by certain reagents, such as ferrous sulphate, contained in a vessel placed in front of the scrubbers.

Candle-power. The quality of gas supplied by gas companies is judged by its illuminating power. This is fixed in London as 16-candle power—that is, one light from gas consumed at the rate of 5 cubic ft. per hour shall be equal in intensity to one light produced by sixteen standard sperm candles. These candles are defined by the Metropolis Gas Act, 1860, as being six to the pound, and burning 120 grains of spermaceti per hour. The gas is burned in a standard burner known as the London Argand No 1, and the light judged by a Bunsen photometer. The gas supply of London is subjected to frequent periodical examination as regards illuminating power, there being twenty testing stations in charge of the London County Council. In 1902 the sperm candles were replaced by a new standard lamp designed by Mr. Vernon

Harcourt, in which pentane (a petroleum distillate) is burnt. Every detail of the lamp is standardised, so that a light of the same intensity is always obtainable, the light being equivalent to the standard candle previously employed. Very precise directions are issued in a publication entitled "Notification of the Gas Referees," which is obtainable from the Government stationers. When gas was made from cannel coal there was no difficulty in supplying coal showing 27-candle power; such gas was used in the Government offices up to about 1876. There was a lower power gas supplied, made from bituminous coal, which tested at 16-candle power, that being the statutory illuminating power at present. As gas is more used for heating, and with mantles, and as it is easier and cheaper to make gas of a lower candle-power, there is a movement on foot among gas companies to obtain consent to supply 14-candle power gas.

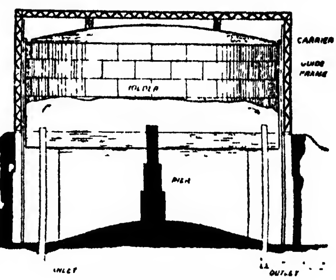
Gas Enrichment. To bring the illuminating power of gas up to standard, it was formerly the practice to employ a certain proportion of cannel gas. The increasing dearness of cannel has led to the devising of other means of enriching gas. The cheapest enricher is benzene, which is volatilised in a special apparatus; toluene, xylene, and naphthalene are better enrichers, but they are not so volatile. The albo-carbon method of increasing the illuminating power of gas at the burner involves the use of naphthalene, which is vapourised by the heat of the gas that is burning. As it is now usual to mix water-gas with coal-gas, the former is carburetted—that is, enriched with benzene or carburine before being added to the coal-gas, and is made the means of adjusting the candle power to standard in the finished gas as supplied to the public. This matter will be referred to again when we consider water-gas.

Gas Testing. To test for *sulphuretted hydrogen*, a strip of lead acetate paper is exposed to the action of a stream of gas for three minutes, when any discoloration that results is evidence of the presence of sulphuretted hydrogen. The lead acetate paper is made by wetting white filter paper with a solution of 60 grains of lead acetate in 1 oz. of water. *Ammonia* is tested for by passing 10 cubic ft. of the gas over glass beads moistened with a known quantity of sulphuric acid of known strength. Any loss of acidity due to the action of the ammonia is tested by another solution of ammonia of known strength. If a complete analysis of the gas is to be made it is conducted in the following order. (1) *Carbon dioxide* and sulphuretted hydrogen, by shaking with caustic soda solution; (2) *oxygen*, by an alkaline solution of pyrogallol; (3) unsaturated *hydrocarbons*, by absorption with a solution of bromine in potassium bromide; (4) *carbon monoxide*, by an acid solution of cuprous chloride; (5) *saturated hydrocarbons*, by partial absorption by paraffin oil, and exploding and analysing the resulting carbon dioxide; (6) *nitrogen*, by mixing a fresh volume of the gas with oxygen, exploding and removing the carbon dioxide and excess of oxygen, when the residue is nitrogen; (7) *hydrogen*, by difference.

By-products. The coke which is yielded from the distillation of coal is employed as a heating agent for the furnace or generator yielding the heat by which the distillation is effected. There is, however, a large excess which is sold as a fuel. If the use of coke as a fuel were more general the smoke problems in large towns would be solved; special grates, however, are required for burning coke effectually. From the gas liquor ammonium sulphate is obtained; it is used as a manure, but large quantities of pure anhydrous ammonia are now required for use in refrigerators. Cyanogen is recovered from the spent oxide of the purifiers. The tar which collects in the tar-well is distilled, and yields a great variety of liquids, which are the starting-point of many aniline dyes and synthetic medicines. Bricks are made from the clinker, and spent lime of the lime from the purifiers; it will be remembered also that iron oxide saturated with sulphur is used for making sulphuric acid. Tar is also used as a paint for outside fences, and when cheap it is economical as a fuel or for enriching gas, as in the Dinsmore process.

Station Meters. When gas leaves the purifiers it is measured by large *station meters*. Gas is measured like any liquid, by alternately filling and emptying an enclosed space of known capacity. The capacity of the space multiplied by the sum of the fillings and emptyings is the volume measured, which is transmitted to a dial. Upon the accuracy or otherwise of the meter depends the record of the yield of gas from the coal employed. The station meter is of the variety known as a *wet meter*, and is of exactly the same construction as the meter supplied for domestic use, but capable of registering very large quantities of gas.

The Gasholder. The gas is finally passed into the large gasholders [6], or gasometers, as they are often incorrectly called. The gasholder is a hollow vessel inverted in a tank of water and maintained in equilibrium by an outer framework or cables.



8. GASHOLDER

The concrete base upon which the gasholder rests is best made of a mixture of old retorts and Portland cement, and the inner surface of the excavation or tank is coated with cement concrete. The gasholder is made of plates of iron riveted together. The different storeys of the gasholder are known as lifts, and slide or telescope within each other, being made gas-tight by water-seals. Gasholders are now made of enormous size, as the larger the holder the cheaper the storage cost. The largest gasholder in the world is at East Greenwich. This is a six-lift holder, and has a capacity of over 12,000,000 cubic ft. of gas. It costs approximately £5 per 1,000 ft. of storage. Spiral gasholders have lifts which ascend and descend with a spiral action. Gasholders equal to at least a day's maximum supply must be provided.

Gas-governor. The gas is now ready for delivery to the public, but, as the demands vary with the time of day and season of the year, an arrangement known as a *pressure governor* is employed to maintain constant pressure on the main. The regulator acts automatically, and is constructed on the principle of a gasholder, in that the rising and falling of a miniature gasholder opens or shuts a throttle valve admitting gas to the main. In large works an exhauster is also required to send the gas through the mains, but in many cases the down pressure of the gasholder is the force which drives the gas through the distributing mains.

Wood-gas. Murdock, to whom we owe the introduction of coal-gas into everyday use, told the Royal Society in 1808 that he had also experimented with wood and peat as a source of gas. The gas which is given off on destructively distilling wood is of good illuminating power if care is taken to employ sufficient heat to decompose the liquid oils which distil over. At high temperatures these yield gaseous hydrocarbons, which contribute in a great measure to the illuminating power. The process of manufacturing wood-gas is practised only in those countries where wood is plentiful and coal expensive. Riche's gas plant is used, the retorts being of cast iron. The gas consists of hydrogen, carbon monoxide with marsh-gas and ethylene, the carbon monoxide being in larger proportion than in coal-gas, some of it being due to the decomposition of the water which is contained in all wood. Sawdust and cork are sometimes distilled for gas, and several methods have been proposed for the preparation of peat-gas. These gases can be carburetted to increase their illuminating powers.

Air-gas. What is known as *air-gas* consists of air carburetted with the vapours of highly volatile hydrocarbons, such as gasoline, carburine, and benzene. The hydrocarbon needs to be very volatile, and of constant and uniform composition. Some small installations in places where gas is not available, and acetylene too expensive, have been successful. At Llanberis School a plant has been satisfactorily working for some time. It consists essentially of three parts: (1) A large, shallow cylindrical copper tank holding 250 gallons, buried some 30 ft. or more from the building, and filled with gasoline through a pipe and closed airtight by a screw tap. Two other pipes, an inlet and outlet, are fitted into the top of the tank, and pass underground to the cellar of the building. (2) In the cellar a pump, worked by a weight on pulleys, forces air through the inlet pipe on to the surface of the gasoline in the tank. Evaporation is rapid—gasoline boiling at from 35° C. to 70° C.—and the mixture of vapour and air is driven through the outlet pipe into (3) an automatic mixer, by which a definite and known quantity of air can be added, so that the proper proportion for burning may be constantly maintained. The apparatus is simple, and requires very little attention. The weight has to be wound up once a week, and the mixer adjusted by moving a small wheel along a rod, about once every two or three months, and the tank filled about every twelve or eighteen months. The frequency of the recurrence of these operations depends on the size of the plant relative to the demands upon it. Some of the air-gas plants require heat to evaporate the hydrocarbon, this increasing in a measure the risks of explosion.

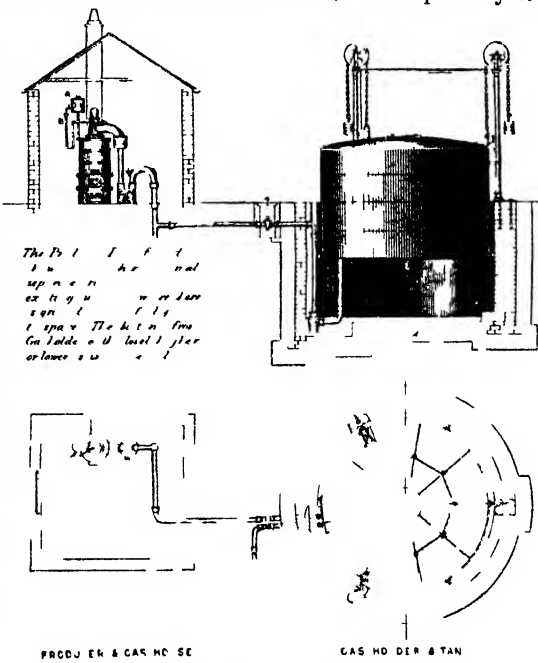
Ether-gas. A similar air-gas can be made with ether, but in this case the air is passed through a box containing a fibrous substance which has been saturated with ether. On dilution with air, ether loses its luminous flame; but any desired degree of luminosity can be imparted by carburetting with benzene. The cost of ether air-gas enriched with benzene is about twice that of oil-gas, its chief advantage being the ease with which a small plant can be installed to meet any temporary requirement. In the ether saturators sometimes employed in optical lanterns oxygen is passed through a metal box filled with ether-saturated cotton-wool.

Oil-gas. When oil is subjected to destructive distillation it is broken up—"cracked" is the technical term—and a gas possessing high luminosity and heating power is obtained. The earliest process was invented by John Taylor in 1815, and shortly afterwards a method of compressing the gas was devised so that it could be readily transported. On account of the last-named fact, the gas was also known as *portable gas*. To chemists this early manufacture possesses an unusual interest, as it was from the liquid condensed in the cylinders of portable gas that Faraday first prepared benzene, this discovery laying the foundation of the aniline colour industry, which has now attained so much importance. The use of oil-gas, however, almost died out on account of the competition of the cheaper coal-gas, and it was not till 1870 that oil-gas was revived as a specially convenient method of illuminating railway carriages, buoys, and lightships.

Pintsch's Apparatus. There are several processes of manufacture. The Pintsch system is one in use by many railway companies, the following being a description of the process as used by the Great Northern Railway at Holloway. The plant was designed to make 60,000 cubic ft. of gas per day. The 10 in. D-retorts in which the oil is cracked are made of 1 in. metal, and are 6 ft. in length; they are worked in pairs, and are kept as nearly as possible at a cherry-red heat. Each pair will make from 300 cubic ft. to 400 cubic ft. of gas per hour, and 600,000 cubic ft. to 700,000 cubic ft. of gas before they require renewal. Immediately before the gas enters the hydraulic main a ¾ in. iron pipe, provided with a stop-cock, is tapped in so that the colour of the gas may be seen, this being the practical test applied to ascertain the quality of the gas, and whether the proper quantity of oil is being admitted. Another test for regulating the supply of oil is to drop a small quantity of the tar from the gas main upon a sheet of white paper; if too much oil is being admitted to the retort, a greasy ring will be found round the spot of tar; but if the right quantity is being used, no greasy ring will appear. The furnaces consume 160 lb. to 180 lb. of coke for every 1,000 cubic ft. of gas produced. The oil used is a once-refined shale oil: it runs to the retorts from a galvanised iron cistern of 50 gallons capacity through a 1 in. iron pipe, at the end of which is fixed a gun-metal micrometer cock for regulating the supply. From this supply pipe the oil flows into a small funnel attached to a ¾ in. syphon pipe, 12 in. deep, connected with the retort; it then falls on a loose tray, preferably of steel, and is instantly converted into a dense brown vapour. The gas issuing from the retorts passes to the hydraulic main, then through air condensers, washers and purifiers into the meters and gasholders. The purifiers contain a mixture of two parts of slaked lime to one part of sawdust placed on wicker trays, and are recharged every week. The cylindrical steel storeholders are 17 ft. 6 in. in length, and 4 ft. 3 in. in diameter: they are tested by hydraulic power to 300 lb. per square inch, and are provided with a pressure gauge registering up to 200 lb. per square inch. The gas is forced into the storeholders through a 1 in. extra strong lead pipe by compressing engines. Each holder is provided with a cock at the bottom for drawing off the condensed hydrocarbon, of which about a gallon is obtained from every 1,000 cubic ft. of compressed gas. Each gallon of oil yields 80 cubic ft. to 85 cubic ft. of gas. The oil is run in at about 12 gallons per hour. Other systems are the Keith, Pope, and

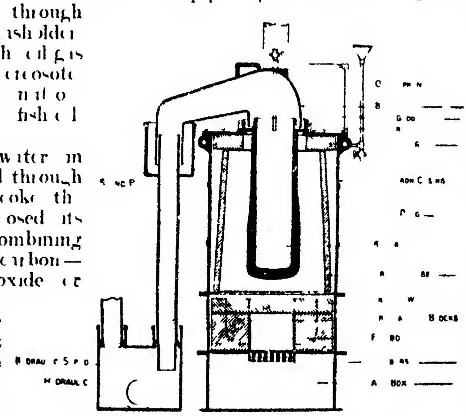
Peebles processes. The object aimed at in the last-named—Young, of Peebles—is to produce an oil gas specially adapted for carburetting water gas and enriching coal gas.

Mansfield's Apparatus. A form of oil gas plant much used for private installations is that made by Mansfield & Sons, Ltd., Liverpool. The illustration [7] shows a sectional elevation of the complete plant, the details of the gas producer being shown in the smaller figure [8]. The producer has a retort suspended in a cast iron casing, lined with fireclay fittings. The top of the retort is made gas tight by a lead joint. When the retort is hot enough to make gas the lead melts, the bonnet sinks into it, thus making an automatic joint. The retort is heated by a coal or wood fire, and a strong red heat as seen through a sight plug is maintained throughout the gas making process. Oil is stored in a suitable tank in any part of the building. From this tank a pipe is led to the oil syphon of the producer. A small cock attached to the end of the pipe regulates the flow of oil which is permitted to run in a fine stream into the funnel of the oil syphon. Through this it passes into the retort, and is converted into gas. The gas rises into the bonnet and passes down the standpipe into the hydraulic main through which it passes into the gasholder. The materials from which oil gas can be made include creosote, palm oil, castor oil, cocoanut oil, Rangoon oil, kerosene, fish oil, tallow, and unrefined fat.



7. MANSFIELD'S OIL GAS PLANT

Water-gas. When water in the form of steam is passed through a mass of incandescent coke the water molecule is decomposed, its constituent elements combining with the coke—a form of carbon—to make carbon monoxide or carbon dioxide and hydrogen. If the temperature of the coke is about 500° C., carbon dioxide and hydrogen are formed, but at 1,000° C. the products are carbon monoxide and hydrogen. The mixture of gases thus obtained is known as *water gas*. In discussing the various combustible and non-combustible constituents of gas, it was pointed out that carbon monoxide is combustible, but that carbon dioxide is non-combustible, and thus of no value as an illuminating or heating gas. The object will be, therefore, to produce carbon monoxide in preference to carbon dioxide if the usual properties of a gas are desired. There are, however, cases in which the carbon dioxide is preferable, as will presently be explained. The reaction in making water-gas takes place in two stages—the first, in which the water molecule is decomposed, absorbs heat in course of the change, and the second, when the carbon monoxide is being formed, is a reaction where heat is given out. The process is on this account an intermittent one. Air is blown in a blast over glowing coke till the mass becomes intensely hot, the gas being given off at this stage being known as *producer* or *generator gas*. When the coke is hot, steam is blown in in place of the air, water gas being produced. The reaction rapidly cools the coke, so that it becomes necessary to stop the injection of steam and again blow the coke to incandescence by turning on the air blast. The producer or generator gas is passed into a second vessel filled with firebricks, which it raises to a white heat, and it is into this second vessel or *superheater* that the steam is passed before it goes into the fuel in the generator. Thus water-gas is made for about four minutes and the heating up occupies about ten minutes. This question of producer gas will be dealt with later.



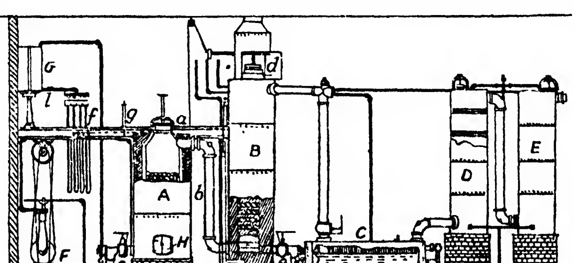
8. DETAILS OF THE GAS PRODUCER

Carburetted Water-gas. It will be remembered that both hydrogen and carbon monoxide give *blue* or non-luminous flames, and to make the gas give a luminous flame it is *carburetted* in a way similar to the enriching process referred to in the article on coal-gas. This carburetting is effected by the hot process in an additional chamber, in which oil is decomposed and the vapours mixed with the water gas in a manner which will be best understood by reference to our remarks on oil gas. The enriching may also be carried out in the cold process by allowing the gas to pass into a vessel containing carburine, a mixture of gasoline and benzene, which vessel is surrounded by hot water

to promote evaporation. This, again, will be readily grasped when the section of this article on air-gas is read. Carburetted water-gas is much used in the United States, where gas-coal is comparatively dear, and hence cannot advantageously be used for preparing coal-gas. In this country the large gas companies are in the habit of mixing about 10 per cent. of carburetted water-gas with the coal-gas as a convenient method of raising the candle-power of the latter to the standard candle-power. Water-gas is more poisonous than coal-gas, as it consists mainly of carbon monoxide and hydrogen, the former a very poisonous gas. Moreover, as water-gas is inodorous, it is not so easy to detect leakage. This objection can be got over by giving the gas a strong smell by passing over naphthalene or impregnating with isocyanides or organic sulphides. The objection does not arise in cases where the carburetted water-gas is mixed with coal-gas, but the poisonous properties of carbon monoxide is a reason why the proportion of water-gas should not be unduly increased. If it were not that the public want a gas to give a luminous flame always it could very well be made luminous at the burner by means of an incandescent mantle.

Advantages of Carburetted Water-gas. After referring to the disadvantages of water-gas, it is only just to state the advantages. These are that the gas can be made of high illuminating power; economy in wages, since fewer workers are required than for the manufacture of coal-gas; the small cost of the installation; small area occupied by the plant; the utilisation of coke; freedom of the gas from ammonia and small amount of sulphur compounds to be removed. There is no need to remove the small amount of carbon dioxide, and the apparatus can be got ready for working in less than four hours, which is a convenience in case of a suddenly increased demand for gas. In coal-gas works it is economical to use the red-hot coke as it is drawn from the retorts.

Lowe's Water-gas Process. Having stated the chief points in the manufacture of water-gas, a few details of some of the processes actually employed may be given. In the Tessié du Motay process the water-gas is made from anthracite (in place of coke) and steam, then purified by passing through a lime-box, and finally carburetted by the cold process, the resulting mixture of water-gas and naphtha, or carburine vapour, being led through specially arranged retorts to ensure decomposition of the hydrocarbon, and finally stored. Lowe's process will be best understood by reference to 9. In this the decomposition of the naphtha is carried out simultaneously with the production of the water-gas—that is, it is carburetted by the hot process. A is the generator, filled with anthracite through the manhole *a*. A fan, F, sends a current of air into the generator through the valve *c*; the gases escaping through the pipe *b* into the superheater B, filled with stacked firebricks; when the gases contain enough carbon monoxide to burn, air is also blown in at the base of the superheater through the valve *e*, the products of combustion escaping into the open at the top through *d*. When the requisite temperature is attained, *c*, *d*, and *e* are closed, and the fan nearly stopped, a very gentle current being still maintained through small orifices in *c* and *e*, purposely arranged to prevent back-rush of water-gas into the air main, which otherwise might cause an explosion. Steam is then turned on at the base of the generator, and a stream of naphtha at the top supplied from the tank by means of a series of distributing tubes. The mixture of hydrogen, carbon monoxide, and a little carbon dioxide formed in the generator, vaporises the naphtha, and the mixed gases act on one another in the superheater, ultimately producing an illuminating gas of high quality, when the steam and naphtha supplies are properly proportioned. The gas is washed in the purifier C, and the two towers, D and E, and stored. The steaming operation is continued for twenty minutes, when the steam is shut off, more anthracite filled in through the manhole, and the cycle of operations begun again. Every few hours (six to twelve) the doors, H, at the base of the generator are opened and the anthracite residue raked out. As will be seen, the product is a mixture of oil and water-gases. All sorts of variations of this process are in use. In one the superheater is filled with lumps of lime to free the gas from carbon dioxide. The Granger plant is arranged so that the naphtha is forced in under pressure, thus facilitating its gasification, and in the Hanlon and Leadley process bituminous coal is used in place of anthracite. Humphrey's apparatus consists of two generators, two carburettors, and two superheaters. The generators are connected by means of a flue, and each of them is also in connection with a carburettor and a superheater, the object being to enable the process to be alternately worked from the left and right.



9. LOWE'S WATER-GAS PLANT

The Dellwik-Fleischer System. In the water-gas processes just described, the fuel is raised to incandescence by blowing air through so deep a bed of fuel that the chief products are carbon monoxide and nitrogen (from the air). One pound of carbon develops only 2,400 heat-units when burnt to carbon monoxide, but 8,080 when burnt to carbon dioxide, for the reason explained in the opening remarks about the water-gas reaction. Carl Dellwik has devised a process by which the products of the "blow" are carbon dioxide and nitrogen, and thus the additional heat-units are made available in raising the temperature of the bed of fuel in place of passing into the producer gas. The result is that twice as much water-gas is obtained, the extra heat reduces the "blow" period, and allows the "run" (steam admission period) to be prolonged. The flow of steam to the fuel is regulated so that even at the end of the run there is no excess of steam to oxidise the carbon monoxide to dioxide. A ton of good coke yields 70,000 cubic ft. of water-gas in place of 34,400 by the older process. Under the older processes the cost of 1,000 cubic ft. of water-gas is from 4d.

to 6d.; by a large Dellwik-Fleischer installation the cost is below 3d. The gas produced by the Dellwik process has been successfully utilised at Cleethorpes for mixing with coal-gas by passing it into the retorts during carbonisation Dr Fleischer improved the original Dellwik process, hence his name becomes to be associated

Methane Hydrogen Gas. This is the name of a process which has been successfully adopted at Sligo and Truro The generator is filled with coke, and then blown up to incandescence, the waste gas escaping part of the way up the generator to the stack pipe, so that the fuel above is dried and heated before it comes down into the hot zone and also serves to filter out the finely divided carbon produced during the run When the requisite temperature has been attained the valves are altered, and steam and tar are injected into the body of incandescent fuel The tar is decomposed into carbon and gaseous products—containing methane—the steam combining with the coke and separated carbon to produce water gas A further quantity of steam injected at the bottom of the generator serves to produce ordinary water gas, which passes away and mixes with the other gases This gas is mixed with ordinary coal gas in the foul main, where it takes up a considerable quantity of illuminants from the hot tar Methane hydrogen is claimed to take up benzene better than ordinary water gas in the carburetting process Such a carburetted methane hydrogen gas costs 8 92d per 1,000 cubic ft at Truro

Producer-gas. This term is applied to the gas obtained in the producer or generator of the water gas apparatus It will be remembered that air was passed into the generator filled with coke a gas was produced which was used to heat the second chamber, into which steam was driven and decomposed into water gas This may be taken as an instance of the utilisation of producer gas, but it finds many employments in metallurgical operations, boiler firing, gas engines and in glass and pottery manufacture It is also known as *Siemens' gas*, because producer gas was economically made in a regenerative furnace of the Siemens type The producer gas is made in numerous different furnaces In some the gas is enriched by being used for distilling coal and again it steam and air are injected a mixture of producer gas and water gas is obtained—the so called *semi water gas* or *Dowson gas* The amount of steam that can be used is limited from the reasons which we have dealt with in the paragraph on water gas—and is arranged so that the heat generated by the air equals the heat absorbed by the steam Producer gas contains a large proportion of nitrogen from the air that is injected and as nitrogen is a non combustible gas producer gas is comparatively poor in heating properties its flame also is non luminous The French call the gas *gaz pauvre*, or *poor gas* Although the gas is poor, it can be produced in large quantities and very cheaply On this account producer gas can be used freely, and still be an economical source of power. Carbon dioxide is also found in producer gas, but the object is to make carbon monoxide in preference, as only the latter is combustible Some average analyses will be given later in comparing the composition of several gases In many producers anthracite is used in place of coal, as the tar produced with bituminous coal entails purification plant, the gas having a clogging action when used in gas-engines if it contains tar.

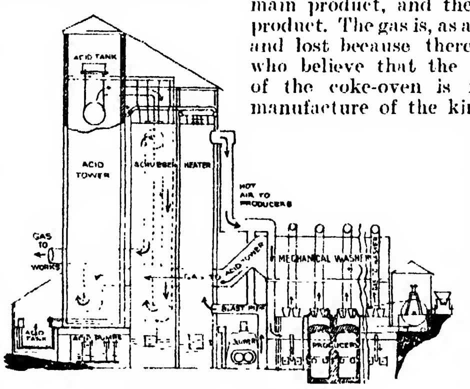
Types of Producers. The Bischof producer of 1839 is the basis of most types that have since been invented The Siemens' gas producer was brought out in 1861 These early types of producers had open ashpits with draught produced as in ordinary furnaces, and much heat was lost Succeeding types are provided with closed hearths, and are produced with numberless variations in the arrangement of the parts Prof A H Sexton divides closed producers into the following five groups (1) bar bottom (2) solid bottom (3) water bottom, (4) automatic (5) blast furnace The Dowson producer one of the best known of the bar bottom type was patented in 1878 (No 3997) and 1881 (No 2839) The air and steam were admitted through the bars The clinker from the fuel accumulates on the bars of the furnace and needs stoking to remove it The Wilson producer of 1876 (No 3949) is an example of the solid bottom producer The fuel rests on the solid bottom of the generator upon a layer of clinker The clinker is drawn off near the bottom and air blown in just above the layer of clinker which is always left in the producer The clinkers are removed every twenty four hours through narrow side doors bars being put across to support the fuel during the operation Solid bottom producers are thus intermittent, but this is got over by arranging a water seal as in the water-bottom producers The ashes fall into water, and no gas escapes The heat of the ashes vaporises some of the water which passes into the producer The Duff producer (patent 15646, of 1901), the Smith and Wincott producer (patent 12895 of 1901), and the Wilson water bottom producer are representative examples of this type In the automatic producers the ashes are continuously removed by mechanical means The Wilson automatic producer does this by a constantly revolving screw, which slowly pushes out the ashes Space will not permit of details being given of the numerous producers that have been patented and which fall under one or other of the above types The chief improvements consist in means of removing the tar from the gas heating the air and steam before use special methods of charging, special arrangements for supplying the air and steam, varieties in grates producers raising own steam, arrangements for breaking up clinker or fuel supplying the air and steam at the top and drawing off the gas lower down feeding at the bottom

Suction Gas-producers. The constantly increasing use of gas engines has ensured the evolution of the gas producers along economic lines The types hitherto dealt with have needed air and steam forcing into the producer with the consequence that the gas was under slight pressure, from which fact the type has been distinguished as *pressure gas producer* From these a new type requiring neither steam jet nor air blower has been evolved the air being drawn into the producer by a suction pump attached to the gas engine, being known as *suction gas producers* With the older type of pressure producers a boiler was needed to generate steam and a gasholder in which to store the gas for use while with the suction type the gas is taken direct to the combustion chamber of the engine The boiler is supplanted by an *evaporator* or *vaporiser*, which in small plants is built frequently on the top of the producer in the form of a water jacket, and in large plants close to the producer in the form of a tubular evaporator This evaporator is generating the steam required by utilising the waste heat of the producer and of the gas, which is of considerable advantage, as

compared with the old system, the firing of a separate boiler being dispensed with. The advantage of a suction gas-producer are automatic generation of the gas by the engine; highest and best utilisation of fuel; no boiler or gasholder required; can be erected without danger in any convenient place; easy to start and to run; no soot, smoke or odour; no explosion possible; and small floor space required. The origin of the type is the Benier producer, which was patented 1894, and has been specially developed on the Continent. A complete suction gas-producer plant consists of a blower which, up to 150-h.p., is driven by hand: a producer, an evaporator, an overflow water-pot, a scrubber, and a small equalising tank or *expansion box*. In plants above 75-h.p. a sawdust scrubber is advantageously inserted behind the wet scrubber, and in plants where two or more engines are fed from the same producer a small gasholder with automatic regulation is used.

The producer consists of an iron shell lined with firebrick and provided with a suitable hopper. The grate area, according to the quality of fuel, is 0·8 to 1 sq. ft. for every 10 horse-power. The scrubber consists also of a sheet-iron shell, and is filled preferably with broken coke. Before starting the engine the fuel in the producer is heated up by means of a blower until the gas is burning well at the test-cock. When this point is reached the blower is stopped, and the engine started in the usual way. The engine then draws by its own sucking action the necessary amount of air and steam through the fuel, and is producing its own power-gas. From the producer the gas is drawn through the scrubber and the equalising tank to the engine. The gas-making process continues so long as the engine is moving, and stops when the engine stops. Anthracite, charcoal, or coke can be used in suction gas-producers.

Mond Gas. Dr. Ludwig Mond, in studying the question of obtaining a cheap fuel gas, has evolved a method in which slack coal is used, and the ammonia produced by the combustion is recovered. The gas is really a producer-gas, but is, on account of the novel method of production, generally distinguished as Mond gas. The gas is being produced on an enormous scale, and is distributed by means of pipes in a large district in Lancashire. The following is a brief description of the plant used, which will be made clearer by referring to the illustration [10]. The producer is provided with a water-seal, and is constructed so as to allow the ash, which is the only residue, to descend into the water, from which it is easily removed without interfering in any way with the working of the producer. The process of combustion is carried out at a comparatively low temperature, with the twofold object of preventing the formation of clinkers in the producer and of providing against the destruction of ammonia. This is accomplished by introducing into the producer a blast of hot air and steam. The quantity of steam required when it is desired to recover the ammonia from the gas is equal to $2\frac{1}{2}$ tons per ton of fuel gasified, but of this about 1 ton is automatically recovered and used over and over again. After leaving the producer the gas is passed through a regenerator arranged so that part of the heat or gas and steam entering it is transferred to the blast of air and steam on its way from the air-heating tower to the producer, the gas being consequently cooled to a corresponding temperature. The gas then passes to a mechanical washer, which further reduces the temperature and removes all soot and dust. The next step is the recovery of the ammonia, and the gas is for this purpose passed through an acid tower, where the ammonia is completely absorbed by a dilute solution of sulphuric acid. The solution circulates through the acid tower again and again until it contains from 36 per cent. to 38 per cent. of sulphate of ammonia. Continuity of the process is provided by adding from time to time fresh supplies of sulphuric acid and withdrawing corresponding quantities of sulphate liquor. The latter is evaporated, yielding at once a solid sulphate of ammonia of good saleable quality. After the gas has been washed of its ammonia products, it passes through a final cooling and cleaning water-tower, and is then ready for use. As the gas is cooled in this final tower the steam with which it was saturated is condensed, and the cleaning water which enters the tower cold is delivered hot; and this, after passing through tar-separators, is again pumped to the air-heating tower to heat the air required for the producer blast. The final cost of 140,000 cubic ft. to 160,000 cubic ft. of gas from a ton of fuel is put at 4s. 11d. About 90 lb. of sulphate of ammonia is obtained from each ton of coal.



10. MOND'S GAS-PLANT

Coke-oven Gas. In the manufacture of coal gas, as we have seen, the gas is the main product, and the coke, although used for several other purposes, is the by-product. The iron smelter requires a coke that is compact, heavy and even, and to produce such a coke special furnaces are used, known as *coke-ovens*. Here the coke is the main product, and the gas given off is the by-product. The gas is, as a rule, completely neglected and lost because there are many iron makers who believe that the recovery of the products of the coke-oven is not consistent with the manufacture of the kind of coke which is most suitable for the blast furnace. As some 13,000,000 tons of coal is coked in the United Kingdom in beehive ovens for the manufacture of pig iron, it will be apparent that the loss is tremendous. Many recovery or by-product coke-ovens have been invented, the principle being that the gas is drawn away from the ovens and means employed to remove the tar and ammonia. The resulting gas can be used for heating the coke-ovens or for other industrial purposes, such as in gas-engines. In large installations of by-product coke-ovens two kinds of gas are separately collected; the richer gas coming off during the first part of the process can be used as an illuminant, the second portion of the coking yielding fuel gas. The other by-products, tar and ammonia, are recovered by similar methods to those used in purifying coal gas, and described a little further back.

Blast-furnace Gas. The blast furnace used for smelting iron ore generates a large quantity of inflammable gas known as *waste gas*. The last name expresses the universal practice of iron makers up to a few years back, when efforts were directed to utilising this wasted form of fuel. The gas, owing to the velocity with which it passes from the furnace, is laden with dust, but this is neglected when the gas is employed for heating the blast, or as fuel under boilers. When required for use in gas engines the gas must be cleaned, or it soon blocks up the valves of the explosion chamber. Properly cleaned furnace gas is an ideal gas for gas engines, as when mixed with air and compressed, it is found to be a slow but very reliable explosive. A portion of the gas is used for driving the gas engine which produces the blast, but much surplus gas remains for other economic purposes.

Composition of Gas. The following typical analyses of illuminating and fuel gas are interesting as showing the relative composition. The figures (percentages) were given by Mr. Willard L. Case in a communication to the New York section of the Society of Chemical Industry in 1905.

from moisture—large quantities in strong iron drums, and small quantities in hermetically sealed tins. This property also accounts for the fact that the storage of calcium carbide is regulated by the Petroleum Act, except when quantities of 28 lb. in 1 lb. packages are stored.

Properties of Acetylene. The light yielded by acetylene more nearly approaches sunlight in light rays, but it has more blue or violet rays (chemical rays). The illuminating power of acetylene is compared with coal gas varies with the type of burner employed. In a suitable burner, 5 cubic ft. of acetylene per hour will give 240 candle power, while the same quantity of coal gas gives 16 candle power. Acetylene is, however, generally burnt in small burners using from ½ cubic ft. to 1 cubic ft. per hour, when the illuminating power is from six to ten times as great as that of coal gas. There is less heat developed by combustion of acetylene for given yield of light than most other illuminants. The distinctive smell of commercial acetylene makes it easy to detect leaks. The limits of explosibility of acetylene mixed with air are 3.1 per cent. to 24.1 per cent., which is a slightly wider range than other combustible gases of commerce. The effects of an explosion would probably be no

Acetylene. At the beginning of the consideration of illuminating gas acetylene was mentioned as both a combustible and luminous gas present in small quantities in coal gas. Acetylene has, within recent years, been prepared for use by itself as an illuminant, this having been rendered possible by the discovery of a cheap method of producing it.

Action of Water on Carbides. When water is brought into contact with calcium carbide acetylene is produced in accordance with the following chemical reaction:

$$CaC_2 + 2H_2O = Ca(OH)_2 + C_2H_2$$

calcium carbide   water   calcium hydrate   acetylene. The production of the gas is so easily and simply effected that it is no wonder that the use of acetylene soon became popular in places where coal-gas or carburetted water gas were unattainable. Besides calcium carbide there are other carbides prepared in the electric furnace but none of them have assumed the importance of calcium carbide. Lithium carbide, barium carbide, strontium carbide, potassium carbide, and sodium carbide all give off acetylene when brought into contact with water, but aluminium carbide gives off methane and manganese carbide, a mixture of methane and hydrogen. Attempts have been made to take advantage of the last-named carbide by mixing manganese dioxide with the ingredients for making calcium carbide, but, so far, the production of mixed carbides has not been successful.

Storage. On account of this action of water on calcium carbide it is necessary that it be stored

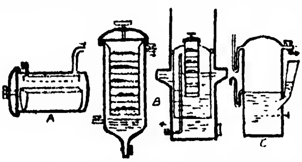
greater than with ordinary gas. Compressed acetylene is dangerous and its manufacture, importation, or storage at greater pressure than 100 in. of water is illegal in the United Kingdom. Acetylene is, however, allowed to be compressed along with oil-gas, as the mixture has been demonstrated to be safe. The exemption extends also to acetylene compressed into porous material, both with or without acetone. The last named liquid has the power of absorbing 250 volumes of acetylene at a pressure of 10 atmospheres, the liquid being known as *dissolved acetylene*.

Impurities in Acetylene. It is the impurities in acetylene which give the gas its unpleasant smell; hence every care needs to be exercised to use only pure ingredients in making calcium carbide. Phosphorus compounds in the lime used become calcium phosphide, which, when moistened with water, yields phosphine; this gives not only an unpleasant odour, but also a white haze of ammonium phosphate in the air when burnt in a closed room. The highest proportion of phosphine ever met with has been 2.3 per cent. Sulphur compounds are seldom present, but sulphuretted hydrogen may be detected in cases where the gas has been improperly generated or where aluminium sulphide is present in the carbide. Crude acetylene always contains ammonia, which arises from the aluminium or calcium nitrite in the carbide. It is an objectionable impurity, as it corrodes the brass fittings, and, producing pyrol at the burners, stops them up. Traces of hydrogen silicide, oxygen, nitrogen (or air), hydrogen, carbon monoxide, and

methane, have also been found in varying small amounts.

Purification of Acetylene. The substances which have been proposed as chemical purifiers for acetylene are (1) ordinary ferric hydroxide, as used for coal-gas; (2) heratol, a solution of chromic acid in acetic or sulphuric acid absorbed in kieselguhr; (3) acagine, a mixture of bleaching powder, with 15 per cent. of lead chromate; (4) puratylene, a mixture of bleaching powder with calcium chloride and calcium hydroxide; and (5) frankoline, a solution of copper and iron chloride absorbed by kieselguhr. These materials have been subjected to an examination and tested for efficiency by Keppeler, and were, as a result, placed in the following order: Ferric acid is practically useless, but one kilo of the other four materials purifies the following quantities (in litres) of acetylene; heratol, 5,000; frankoline, 9,000; puratylene, 10,000; acagine, 13,000. In practice, these numbers may be increased from 10 per cent. to 20 per cent.

Types of Generators. There have been up to the present time some hundreds of different apparatus [11] constructed for the purpose of generating acetylene from calcium carbide. These have been classified by Professor V. B. Lewes into the following three classes, into one or other of which all the generators at present on the market fall.



11 TYPES OF ACETYLENE GENERATORS

1. Those in which water is by various devices allowed to drip or flow in a thin stream on to a mass of carbide, the evolution of the gas being regulated by the stopping of the water-feed.

2. Those in which water in volume is allowed to rise in contact with the carbide, the evolution of the gas being regulated by the water being driven back from the carbide by the increase of pressure in the generating chamber.

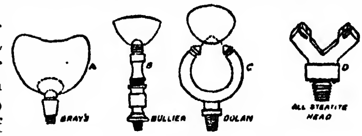
3. Those in which the carbide is dropped or plunged into an excess of water.

These types are again subdivided into (*a*) *automatic* and (*b*) *non-automatic*.

By automatic generators are meant those which have a storage capacity for gas less than the total volume which the charge of carbide is capable of generating, and which depend upon some special contrivance for stopping contact between the water and carbide. Non-automatic generators are those in which a holder of sufficient capacity is provided to receive the whole of the gas made from the largest charge of carbide which the apparatus is capable of taking.

Choosing a Generator. The factors to consider in choosing a generator are those which guided the Departmental Committee appointed to advise the Explosives Inspectors in 1900. The Committee consider that in selecting an acetylene generator regard should be had to the following desiderata: (1) simplicity of action and design; (2) strength of construction; (3) high efficiency, as indicated by the yield of gas per lb. of carbide; (4) low pressure in generator; and (5) facility of removal of the residue.

Acetylene Burners. One of the chief difficulties in the burning of acetylene is the quantity of smoke which is produced, which causes endless trouble by growths of carbon which form at the tips of the burners. Burners using 0.75 cubic ft. to 1 cubic ft. of acetylene per hour are the largest that can be used without unpleasant effects. The acetylene is mixed with air at the burner in the most successful type, an air intake being arranged at the tip of the burner. The Naphey is a popular kind. In this, two small jets of acetylene meet to form a flat flame, with very little tendency to produce smoke or become choked. Other types are shown in 12.



12. TYPES OF ACETYLENE BURNERS

Installation Hints. As there are many points of difference between the fittings used for coal-gas and acetylene, the requirements are briefly indicated separately. The generator and holder should be in a well-ventilated place outside the house, the place being capable of being warmed with hot-water pipes in case of severe weather. The holder should be of such a size as to contain sufficient gas to last the whole evening or the longest period the burners will be alight. As regards the size of the pipes used for supplying acetylene, it must be remembered that a given size pipe will supply three times as many burners with acetylene as with coal-gas. For fifteen burners ½ in. pipe is used; for sixty burners, ¾ in. Iron barrel piping should be used, and joints screwed together without paint or packing. Taps require to be of best quality brass, as cheap fittings are soon corroded. In starting an installation, care must be taken that all the air is out of the pipes. It is best to take samples of gas from each burner in a test tube, and test with a match before applying a light to the burner for the first time. The pressure at which the gas is supplied should not be more than 2½ in.

Yield and Cost of Acetylene. One pound of calcium carbide will yield 5 cubic ft. of acetylene; in practice it is usual to reckon the quantity as 4 cubic ft. Acetylene is reckoned to cost £2 per 1,000 cubic ft. in the holder, and if it is distributed on a commercial scale, the cost of distribution will double this. Coal-gas costs 1s. 2d. per 1,000 cubic ft. in the holder, this being doubled by the expense of distribution and profit. It will thus be seen that acetylene cannot displace coal-gas where the latter is obtainable.

Acetylene Lamps. Many kinds of portable acetylene lamps have been devised, but the great difficulty in the case of table lamps has been to ensure freedom from smell. It will be obvious that similar conditions and principles apply in constructing table lamps as are indicated in the case of generators. It is usual to arrange a filter of silicate wool before the acetylene is passed into the burner, so as to guard against mechanical impurities being taken into the flame. Acetylene cycle lamps are much in use on account of the brilliant illumination obtained. Such lamps are more expensive to maintain than oil lamps, and the greater light obtained is not always a recommendation. Acetylene motor lamps are a development of the cycle lamps.

Gas Meters. To measure the quantity of gas used by a consumer, gas is passed through a meter which mechanically records the volume of the gas. The meter is fixed within 2 ft. 6 in. of the main cock. The gas is measured in cubic

feet, for which, curiously enough, no standard existed till the passing of the Sale of Gas Act 1859 This Act fixed the standard cubic foot as the space occupied by 62·321 lb avoirdupois of distilled water, weighed in air at 62° F, and at normal atmospheric pressure Meters are tested for accuracy by passing through them a measured volume of gas from a small gasholder The following are the capacities of a few ordinary size meters

Size	[illegible] inlet and outlet [illegible]	Measuring [illegible] per [illegible]	[illegible]
	in	ft	ft
10 light	1	½	60
20 ,,	1¼	1	120
30 ,,	1[illegible]	1½	180
51 ,,	1½	2½	300
100 ,,	2		[illegible]00
250 ,,	4	12½	1 [illegible]00
1 000 ,,	7	[illegible]0	6 000

Wet Meters. There are two types of meters in use, the wet meter and the dry meter The former is constructed on the model of the station meter and consists of three essential parts (1) a hollow drum or wheel rotating in water through this drum the gas passes, and as the drum rotates it actuates the dial index recording automatically the gas passed, (2) a compensating arrangement for keeping the chamber in which the drum revolves at a constant level and (3) the index which shows the amount of gas passed The measuring wheel is of inflexible material, but the water in the meter is liable to freeze in cold weather For this reason the meter requires to be protected from change of temperature and as an additional precaution glycerine is added to the water to lower the freezing point Salt, magnesium chloride and calcium chloride are sometimes used in place of glycerine but corrosion of the interior of the meter often results

Dry Meters. This type of meter works on the principle of an ordinary bellows Gas enters and leaves compartments having flexible leather sides alternately through valves which open and shut at the proper moment One of the best known makers of dry meters thus describes his make of dry meter

It consists of a cylinder divided by a plate in the centre into two separate cylindrical compartments which are closed at the opposite ends by metal discs these metal discs serve the purpose of pistons and they are kept in their places by a kind of universal joint adapted to each the space through which the discs move and consequently the means of measurement is governed by metal arms and rods, which space when once adjusted cannot vary To avoid the friction attending a piston working in a cylinder, a band of leather is attached which acts as a hinge and folds with the motion of the disc this band is not instrumental in the measuring so that if it were to expand or contract, the registering of the meter would not be affected, inasmuch as it would only decrease or increase the capacity of the hinge the disc being still at liberty to move through the required space the leather is also distributed in such a manner being curved and bending only in one direction that it prevents any creases or wrinkles forming, and renders it therefore much more durable The arrangement of the valves and arms are somewhat different to that of the steam engine, although somewhat similar in principle

Most dry meters are composed of two chambers, but there may be three or more, without difference of principle The chambers fill and discharge alternately or in succession, and the action of the valves is accurately registered in the mechanism that regulates the dials of the index. A common error is the supposition that the leather enclosing the space between the discs actuates the gas, but the whole of the work is performed by the latter, which are really pistons receding to let the gas fill the chamber and advancing to drive it out Though delicately adjusted, the mechanical action is really very simple

How to Read the Meter. There is no mystery about the dial of a gas meter It is perhaps because some people have never considered the subject that they think it difficult to read a gas meter. It is as simple as telling the time by a clock There are three or more dials in the little compartment at the top of the meter One of these indicates, perhaps 2 cubic ft an arrow usually being placed to indicate the direction of the hands When a large quantity of gas is being burnt the little hand in the unit dial is kept busy and the consumer can get a good idea of the cost per hour of, say, a cooking stove The other dials register hundreds, thousands, ten thousands and million cubic feet the hands moving on the dial just as on the smaller dial, but naturally much slower At a given date—say, the beginning of a month—the quantity is noted, and at the end of the month the index is again read off the difference between the two amounts being the quantity consumed during the month In the case of illuminating devices used at public rejoicings the gas is generally taken direct from the main and a charge made of so much per jet per hour, with a minimum charge of 50s

Prepayment Meters. These meters, which are actuated by a coin are also known as slot meters They were invented in 1887 and are of various kinds—Brownhill's Price's Cutler's Braddock's, Cowan's Glover's and Parkinson's—adapted for taking either pennies sixpences shillings, florins or half crowns The slot meter is extremely popular with people of moderate means who can thus use a cheap illuminant without running into debt

Slot-meter Mechanism. At the front of the meter is the slot Within is a delicate balancing arrangement which works on the valve of the meter This balance is connected with the index and as soon as the drum cylinder has revolved the allotted number of times the balance is disturbed and the coin drops down and the supply ceases As meters are made to give out quantities of gas for a six pence a shilling a florin or half a crown it is easy to see that the weight of the coin, except as a means of starting the action has nothing to do with measuring the gas

Gas-fitting. From the meter pipes convey the gas to the various parts of the house The supply pipes are best of wrought iron but composition pipes are much used The latter are more liable to damage and many cases of leakage have been caused by nails having been driven into the softer piping The liability to compression and consequent constriction in the supply of gas is another fault often found with composition pipes Cheap piping is to be avoided as soundness is a very necessary quality in gaspipes All lines of piping should be laid with a gradient so that condensed moisture can drip or drain back into the risers Drip pipes should be provided where necessary Piping should be exposed as much as possible to facilitate future examination and where the pipes are laid beneath floors the boards should be screwed and not nailed down In searching for leaks in pipes, a light should not be used, but the suspected parts painted with a strong soap solution, bubbles will show themselves if the least trace of gas is escaping The work of the gasfitter has been described on pages 5797 to 5799

GAS *concluded*

BUSINESS SIDE OF GARDENING

Economical Gardening. The Oldest Profession on Earth. Nurserymen and Seedsmen. The Market Gardener and his Opportunities. Profits and Losses

By H. H. HAVART

WHETHER a garden be large or small, its economical management depends so much on soil, situation, and other circumstances, that no hard and fast rule can be laid down to apply equally in all cases. Particularly does this apply to suburban gardens. There are some, notably in the western suburbs of London, attached to houses built on the site of market gardens, the soil in which is naturally good, and where but little in the way of manure is needed every year.

The Cost and Economy of the Small Garden. The initial cost of forming such a small garden, too, depends greatly on the condition in which the builder of the house has left it, or, if the house is not a new one, on the horticultural tastes of the previous tenant. Assuming that the ground is not in a very rough state, the following figures will serve as a guide to the initial outlay necessary:

	£	s.	d.
Jobbing gardener, two days weeding, digging, and preparing ground at 5s. per day	0	10	0
Spade, rake, etc.	0	8	0
Lawn mower	0	14	6
Loam, leaf mould, potting soil, for improving ..	0	12	6
Manure	0	6	0
Small collection of vegetable seeds	0	2	6
Small collection of bulbs	0	5	0
Small collection of hardy annuals and perennials	0	5	0
Fruit and rose trees and shrubs (say)	1	0	0
	£4	3	6

This figure does not, of course, represent the annual expense, which may, in subsequent years, be limited to practically the 12s. 6d. comprising the seed and bulb items, as fruit and rose-trees rarely require renewing. The item for manure, too, is one which need not recur often. In fact, in many cases, a tradesman who supplies the household with goods will be only too glad to give a load or so of horse manure, if asked for it.

A greenhouse, with its accompanying heating apparatus, and a frame constitute a serious item. An efficient greenhouse for a small garden would be one (say, 9 ft. by 6 ft.) costing about £4, and the necessary heating apparatus another £3. A handy-sized frame, 8 ft. by 6 ft., costs £2 15s. The prices given are those for the simplest form of house and frame, and may be taken as being the lowest at which an effective greenhouse can be established.

Economy in Vegetables and Fruit. The most economical thing that can be grown in any small garden is undoubtedly the scarlet-runner bean. A shillingsworth of these, sown at intervals of a fortnight throughout the spring, will yield sufficient for the needs of a small family throughout the summer, and on into the autumn—that is, assuming that they take their turn with other vegetables. It is waste of time to try and grow such vegetables as cauliflowers and cabbages in a town garden. Radishes, lettuce, and mustard-and-cress are most economical vegetables for town-garden culture, and, at a rough computation, a shillingsworth of crop may be expected for every pennyworth of seed sown, provided ordinary care is used in thinning out and other details.

Pears thrive in town gardens much more readily than apples, while crops of cherries and plums are usually spoiled by the attacks of birds. Of the bush fruits, the gooseberry is most likely to yield a profitable crop under such conditions. Strawberries are not to be thought of except as a hobby, as they take up a large amount of ground for a yield which is small in comparison. The ground they would occupy is best covered with small saladings.

Economy in the flower garden is to be effected by its help in furnishing flowers for indoor decoration, and for "buttonhole" purposes. In planting a small garden for economy, it is not at all necessary to put the things in formal rows, as if planting for market purposes. Those flowers which yield large supplies of bloom for cutting purposes should be interspersed with such things as geraniums, calceolaria, lobelia, and the like, which, though not so adapted for filling vases, lend bright colour to the garden generally: hence, when occasion arises to cut the flowers in the garden with a free hand, the presence of the things just mentioned will conceal the bareness which their absence would only serve to accentuate.

Economical Management of a Large Garden. The economical management of a garden depends almost entirely on the selection of a head gardener, and in this connection it often happens that the best horticulturist is not the man most suited to control a staff economically, and get the maximum amount of produce out of the ground at the minimum expenditure of money.

A young gardener who hopes to rise as high as possible in his profession should be careful not to lose sight of the commercial side of it. The days when an owner of a country seat simply gave orders for a garden beautiful, without counting the cost, are over. Certainly, owners of gardens take much more personal interest in them than hitherto, but the commercial spirit of the age has entered into gardening as deeply as into many another hobby, and, although it seems sordid to say so, the head gardener who can make the biggest show of bloom at the cheapest rate is the man who will get on.

Economy in labour is one of the most important items in the management of a large garden, and here the individual who calls himself a "head working" gardener will be out of place. In an establishment of any pretentions, where the number of hands employed in the gardens may be anything from twelve to forty, it is a false economy on the part of the head, as a rule, to do any of the manual work himself. It must not be forgotten that, in the majority of gardens, a large section of the staff will be composed of boys and young men, with little or no sense of life's responsibilities, and that the temptation to idle away their time when no watchful eye is upon them is one too great to be resisted. Instead of actually doing things himself, therefore, the head gardener should spend a large portion of his time in seeing that others do them as he would wish. It is a false economy to employ young and comparatively inexperienced men as foremen. Next to the head himself the well-doing of the garden is in the hands of

these men, and, though it may look well on paper to show a few pounds saving at the end of a year in this part of the wages list by employing low-priced hands, it is of very little use when there is a much bigger item on the other side of the balance-sheet for plants and other things which have been spoiled by careless handling.

Seed-saving. An important item in the management of a large garden is that of seed-saving. Seed of all flowers and vegetables that do well in a garden should be saved every year, and be stored away for sowing the following season. Careful attention to this branch of the garden work will effect a saving of many pounds on the annual seed bill, and the work of picking them over in order to separate the good from the bad is an operation which may readily be carried out during the winter days when there is not so much to be done out of doors, or at any time when inclement weather causes a cessation of operations outside. It is not economy to be constantly introducing novelties into a garden. Changes must, of course, be made from year to year, but thousands of pounds are wasted annually in this country in the purchase of seeds, plants, and bulbs which are boomed as being something new.

It is not too much to say that an economy of 25 per cent. can be effected in the cost of fuel for the hothouses where care is used. Sufficient fuel must, of course, be used to maintain the houses at an adequate temperature, and anything more than that is not only waste as far as the consumption of fuel is concerned, but is not in any way conducive to the welfare of the inhabitants of the greenhouses. It should not be forgotten that coal-dust, damped with a little water, and banked up in the boilers overnight, will preserve an equable temperature in a house till morning, without further attention. This is a far more economical plan than the general one of stoking up overnight with a mixture of coal and coke, which invariably has the effect of raising the house many degrees above its proper temperature during the early hours of the night, and letting it down dangerously by the time the darkest and coldest hour of all arrives—the one preceding dawn.

A watchful eye must be kept on what is erroneously called the rubbish heap. It is a common practice to throw away bulbs that have been forced, plants which have been pulled up in the process of thinning out beds, and other such things. All forced bulbs may be used again in a spot in the reserve garden to furnish a supply of bloom for cutting, and if there is no room for surplus bedding plants, or thinned-out vegetables, they may readily be exchanged or got rid of in other ways.

How to Label. Proper labelling of plants is a far more important factor in the economical management of a garden than is generally imagined. Except in the case of plants which are so generally grown that they cannot fail to be recognised by the merest tyro, it is well to have everything labelled inconspicuously, but at the same time clearly. This is particularly important in gardens where collections of the different species of a genus are made, as, although many of them are very similar in appearance, they require different treatment from each other. In the event of a mistake, therefore, it is easy to see that a lot of valuable plants may be lost through not being labelled at all, or labelled indistinctly. It may be well to state here that the writing on a label should always be commenced at the top end—that is to say, at the part of the label furthest from the point which sticks into the ground. The reason for this is that if the rain and decay tend to make the label illegible, the upper part of it is, in the ordinary course of events, sure to be clearer than that which is close to the ground. If this upper part, therefore, bears the first part of the name of a plant, it is usually easy to guess at the remainder; but if the writing of the label has been started at the lower part, in all probability the last few letters of it only will be legible, and confusion easily follows.

The Need for Tidiness. It need perhaps hardly be said that tidiness and economy go hand in hand in gardening. All such operations as weeding, rolling, mowing, the clipping of hedges, and the hundred and one operations which go to make the garden neat and pleasing to the eye, should be attended to promptly and frequently. It is easy for a lad to remove young weeds, for example, in a very short time when they first make their appearance, but if they are allowed to remain undisturbed for a few days, it is astonishing with what rapidity they will grow, and with what corresponding difficulty and expenditure of labour their removal will be attended. That well-known business maxim, "Do it now," cannot be too rigidly observed in connection with the gardening operations just alluded to if a true economy of time and labour is to be effected. On the other hand, it is well not to be too precipitate with the autumn and winter planting operations, and the carrying out of such schemes as summer bedding. The vagaries of the weather have to be considered here, and too much promptness in the work may allow a nip of frost to destroy everything, and hence, instead of an economy being effected, a further expense for new plants is incurred.

How to Become a Gardener. Although the oldest profession on earth, gardening is one which is most poorly paid, and the lad who is setting out with the determination to make a fortune should think very deeply before he decides to embrace horticulture as the means to that end. This remark applies more particularly to private gardens. There are plenty of instances on record of nurserymen who have accumulated large fortunes, and, although the market gardener is always pleading poverty, one very rarely sees members of his profession included in the official list of Receiving Orders in Bankruptcy; but in both these businesses there is, of course, a large element of risk. To qualify as a gardener it is necessary to start young. The orthodox way is to secure a berth in some large local private garden or nursery as a boy, at a wage which rarely exceeds 5s. per week. If a lad shows any aptitude the head gardener will be only too glad to push him on, and, in a couple of years time or so, his money will be raised to 7s. or 8s. a week, in addition to living accomodation in the "bothy." This "bothy" is usually a small cottage in which the young unmarried gardeners in a private establishment live together, and take it in turns to act the part of housekeeper. If the "improver," as the embryo gardener is called at this stage, lives at home instead of in the "bothy," he is usually paid a shilling or two more per week. As he grows older and gains more experience he develops into a "journeyman." There is no doubt that at this time he gains the bulk of his experience, and if he wishes to learn his profession thoroughly he will do well to change his situation occasionally, and become acquainted with gardens in various parts of the country.

It must be distinctly understood here that the writer does not wish to advise lads and young men to throw up good situations, and go wandering about the

face of the land in and out of work every few weeks. If a gardener is in a situation which seems likely to be a permanent one, and the prospects of promotion are good, he will, of course, stay there if he is sensible. At the same time, experience gained in only one garden cannot be so varied or valuable as that obtained in two or three, where soil, aspect, climate, and dozens of other conditions vary.

Getting to the Top. By the time he is four or five and twenty years of age, the "journeyman" usually considers he has sufficient experience to dub himself a "foreman," and in this capacity he has charge of one part of the garden, under the immediate supervision of the head gardener. The number of foremen employed in a garden varies, but in a place of any pretensions there is usually one for the kitchen garden, one for the flower garden, and a third for the glasshouses and conservatories. His wages are now about £1 per week, and his share in the "bothy," or 24s. a week, roughly, if he lives outside. The final step from foreman to head gardener usually happens automatically, when the horticulturist is lured into matrimony. He finds that a foreman's wage is not sufficient to support two, and therefore he endeavours to better himself by applying for a situation as head gardener. When he has succeeded in obtaining this he has risen as high as he can ever hope to do in his profession. His emoluments now consist of a salary of 30s. a week with a cottage to live in rent free and the privilege of having sufficient of his employer's coal, fruit, and vegetables, for the consumption of himself and family. There are very few gardeners indeed in the United Kingdom who, though they may have charge of places in which thirty or forty men and boys are at work, receive a higher wage than that just mentioned, an income which, in cash and kind, rarely exceeds £150 a year.

Growing for Exhibition. Growing for exhibition at flower shows is another of the gardener's methods of increasing his income if his employer does not object. There is hardly a village in the United Kingdom that does not hold its annual flower-show, and many gardeners exhibit at every show within a reasonable radius. The prizes are not large, certainly, ranging as they do from a shilling to a sovereign, but they amount to a considerable aggregate with a consistent exhibitor. The majority of employers are very willing for their gardeners to compete at these flower shows, and willingly buy exhibition varieties of different plants to facilitate their chance of winning, thinking, as they rightly do, that success at flower-shows is a proof of the skill of their gardener, and an incentive to spur him on to further efforts. At the same time, however, it must be remembered that too much showing is a bad thing. A head gardener who is constantly exhibiting is apt to devote too much attention to his "show" plants, to the detriment of the garden work generally, while his constant absence at the shows themselves, brought about by the necessity of staging and removing his exhibits, is likely to make things get slack in the garden all round. Exhibiting, therefore, should only be done in moderation.

How to Succeed as a Nurseryman and Seedsman. The difference between a florist and a nurseryman and a seedsman is a simple one. The florist is not a producer, but is generally merely an agent for the disposal of goods grown by other people. The nurseryman and seedsman, on the other hand, sells plants and seeds which are the result of his own cultivation and skill. It must not be imagined, however, that nurserymen sell nothing but what they have raised themselves, as large quantities of seeds and bulbs are imported annually, chiefly from Germany, France, and Holland, to enable them to fill orders which they could not execute from stock of their own raising [see also SEEDSMEN, page 4995].

Roughly speaking, nurserymen and seedsmen may be divided into three classes. At least 70 per cent. of them do the bulk of their trade in penny and twopenny packets of seeds, and cheap bedding plants. About 20 per cent. of the remainder have a better class of trade, an important feature of which is the laying out and keeping in order of suburban gardens by contract. The remaining 10 per cent. or thereabouts represent the elite of the trade, who, as a rule, supply only seeds of the finest quality, grown by themselves, and the latest novelties, for which they can command high prices.

How to Start. At the present time, undoubtedly the best situation for a nurseryman and seedsman who contemplates starting in business is in the outer suburbs of London or one of the other great cities. In such a situation he will be able to grow plants and produce seeds, free from the taint of city smoke, though, at the same time, they will be hardy enough to withstand the rigours of town life. A large portion of his trade will be purely local, although the postal department of a nurseryman's trade is one which ought never to be neglected. Naturally, the greater portion of the stock of a seedsman who caters for the million will have to be purchased by him from the wholesale houses in bulk, and made up and retailed in small quantities. Much of the success of the retailer will depend on the quality of the seed he thus dispenses. If he is careful to deal with wholesale firms of high standing, whose names are a guarantee of the goods they supply, our young nurseryman is, at all events, sure of giving satisfaction to his customers.

A certain amount of seed of such things as calceolaria, petunia, lobelia, and other popular plants should be sown very early in the year in heat with a twofold purpose in view. Some of the plants so raised will be required in the late days of spring and early summer, either for selling to chance customers, or for the purpose of fulfilling any contracts to keep gardens and window-boxes in order which the nurseryman may have been fortunate enough to secure. Keeping gardens in order by contract is a very profitable branch of a nurseryman's business, and a good trade may often be done in this direction by a local canvass of likely houses during the months of April and May.

Mail Order Business. If this branch of his industry should at first not come up to his expectations, there is another channel through which the nurseryman can dispose of any plants he may have on hand. This is by means of advertisements in the horticultural journals, bearing always in mind the fact that the nurseryman should draw up his advertisement with a view to disposing of what he will have ready for sale in a fortnight or three weeks' time. Most horticultural journals go to press at least a week in advance, and the consequence is that plants, which may be ready for disposal at the moment of drawing up the advertisement, will be past their best time for transplanting when the announcement is made public, and orders begin to come in. Intelligent anticipation will do much to assist in this branch of the business, but if, as sometimes happens, an unexpected storm or a late nip of frost injures or destroys the plants upon which

hopes of profit have been built, the best plan is to return the money for orders which cannot be filled from the nurseryman's own stock.

The Bulb Trade. The large majority of bulbs sold in this country every autumn are of Dutch origin, though within recent years it is pleasing to know that in the Lincolnshire Fen district, and in some parts of Ireland, bulb culture has met with no uncertain measure of success. Comparatively little wholesale trade is done, however, as most of the growers supply the public direct. In the days to come, however, there is but little doubt that the English and Irish bulbs will oust the Dutch bulbs from the market, especially as far as the better and choicer sorts are concerned. In the meantime, it is well to deal only with Dutch firms who will guarantee their bulbs as being true to name. A nurseryman should never hesitate about stocking bulbs liberally, as he has two chances of selling them. Those which are not got rid of by the end of November, when all bulb planting should cease, should be potted up and hurried on in a slight heat, when they will readily sell in the very early spring for decorative purposes, as the garden, and often the greenhouse, are comparatively bare of flowers at this time of the year unless they have been well looked after.

It should not be forgotten that one of the most profitable branches of a nurseryman's business is the "buttonhole" trade. To cope with this branch as far as possible, special efforts with winter-flowering carnations and roses in pots should be made, as these two flowers are in the greatest demand. If sufficient cannot be grown on the premises, without undue encroachment on valuable space, supplies may easily be augmented by French and Channel Islands flowers, which arrive at Covent Garden Market and other great centres of distribution in large quantities during many months of the year.

The Market Garden. The market gardener is not troubled much by winding paths and pretty effects. Concerning that part of his ground which is destined for open-air culture, the great aim of the market gardener, after such ground has been dug and prepared, is to maintain a proper rotation of crops, especially as far as vegetables are concerned. To this end the same vegetable will be grown on the same piece of land only once in every fourth year, so that the different chemical elements in the soil may adjust themselves and preserve the ground from becoming impoverished, at the same time effecting a large saving in the bill for animal and artificial manures.

There are a few points of especial importance if one wishes to succeed as a market gardener. It is well, to some extent, to specialise. A man stands a far better chance of success if he goes in for growing just a few things; say, for the sake of argument, grapes, tomatoes, and the choicer stone fruits on a large scale, than he does if he potters about with little patches of half a hundred different things which have cost him far more, in proportion, to bring to perfection, for which he will have a difficulty in finding a market. Salesmen do not care to handle small parcels of goods of which the carriage practically swallows up the profits.

The Opportunities of Extra-season Crops. Another point which the market grower should watch is not to devote all his attention to "main crop" things, but pay attention to early and late sorts. For instance, who has not lamented the shortness of the strawberry season? To the man in the street it is heralded by the appearance of choice fruits at two or three shillings for a small basketful. In a fortnight's time there is such a glut of the berries that really excellent fruit may be purchased at fourpence or sixpence a pound, and then all is over, and what cannot be eaten has to be destroyed or rushed round to the jam factories.

If many of these growers had devoted their attention to earlier and later sorts, there would have been a longer and steadier demand at better average prices, and less risk of the fruit spoiling without finding a purchaser. There is no difficulty about this. At the headquarters of the strawberry world, close to Bedford, it is quite possible to have strawberries any day in the year, and though an all-the-year-round strawberry trade is not to be recommended, it would be quite easy to lengthen profitably the present season.

Raising New Varieties. The raising of new sorts of fruits and vegetables can be made a source of profit to the market grower. Potatoes, for example, lose their character in the course of a dozen or twenty years and give way to disease, while tomatoes, strawberries, and many florists' flowers, such as roses, chrysanthemums, and carnations also deteriorate in quality and need to be replaced by good new sorts. It is a fact that a couple of seasons ago the now world-famed Eldorado potato changed hands at the rate of £22,400 a ton, while another variety, Northern Star, was for a brief period sold at the rate of £4,500 a ton.

When laying out the market garden, however, it is not wise to reserve too large a piece for experimental purposes. To attempt to raise an improved new potato is very much like taking a ticket in a lottery, there are so very few prizes and so many blanks. Cautious growers, who have made up their minds not to soar above the limitations of a moderate income, will carefully ignore the experimental ground altogether, and content themselves with buying stock of any desirable novelty from the lucky raiser.

The Profit and Loss Sides of a Market Garden. Within the last few years many thousands of acres of agricultural land have been diverted from the purposes for which they have hitherto been employed, and used for raising crops of fruit and vegetables for market. The Board of Trade returns show that this acreage is increasing every year, a fact which goes some way to show that the occupation is a profitable one, an assumption which is further borne out by the curious reticence of professional market gardeners at all times to give any reliable figures for publication.

As far as his profit and loss is concerned, the market grower is largely at the mercy of the weather, and it is not only bad weather that he has to fear. Storms, winds, and other inclemencies, will, of course, retard progress and tend to produce only scant and immature crops—a source of considerable loss, as the expenditure for labour, manure, and materials is just as heavy as in the case of a generous yield. Too favourable weather also is not a source of unmixed satisfaction to the market grower. It means a full crop, certainly, possibly a glut, and when this happens the prices realised immediately fall so low that there is little or no profit for the grower.

In all market gardens where there is a large amount of glass for growing cucumbers, tomatoes, grapes, and other such things, there is always danger during severe weather of damage due to breakage. A single hailstorm has been known to do £20,000 worth of damage to glasshouses alone, in addition

to which, tens of thousands of tender plants perished at the time from exposure Every market gardener should guard against loss from this source—and it is a more frequent danger than is customarily imagined—by insuring his glass house against damage by the weather Several companies will take such risks at a moderate premium, and one in particular specialises in them

When starting in business, the young market gardener should be careful to ascertain that he is properly rated as, if his holding is of any size such rates will form a considerable item in his profit and loss account Market gardens are only to be rated at one fourth of the amount in the pound which is payable for a dwelling house—that is as far as the general urban district rate is concerned For a Poor

garden, and the return that may be expected from each crop.

The table given below has, however, been carefully prepared with a view to showing the average returns which may be expected from land carrying the various vegetable crops, and will, at all events, be of assistance to the novice who is in doubt as to whether he is managing his market garden in an economical manner

In the item "cost of cultivation" in the table no provision has been made for the cost of manuring Here, again, no hard and fast rule can be laid down Where plenty of natural manure is obtainable, the use of much chemical or artificial manure is not recommended In most cases, however, the soil of market gardens needs a stimulant

AVERAGE YIELD OF MARKET LAND, COST OF CULTIVATION AND MARKET PRICES

	Average yield per acre	Cost of cultivation per acre	Average market price
Artichoke (Globe)	1[illegible]000 heads	Approximately same as cabbage	1s [illegible]d per doz
Artichoke (Jerusalem)	[illegible]0 bushels	Approximately same as potato	2s 6d per bushel
Asparagus	[illegible] cwt	Varies widely	1s to [illegible]s per bundle (100 shoots)
Beans (broad)	120 bushels	Varies widely	[illegible]s 6d per bushel
Beans (kidney)	[illegible]0 bushels	Varies widely	[illegible]s per bushel
Beetroot	3[illegible]0 bushels	24s per acre	[illegible]d to 2s per doz
Broccoli	8 to 10 tons	Same as for cabbage	10s per crate of 6 doz
Brussels sprouts	1[illegible]0 bushels	From [illegible]0s to [illegible]s per acre	[illegible]s per bushel
Cabbage	10 000 heads	[illegible]4s to [illegible]8s per acre	1s per doz
Carrots	[illegible]00 bunches	70s per acre	3s 6d per doz bunches
Cauliflower	1[illegible] to [illegible]0 [illegible]	3[illegible]s per acre	[illegible]s per doz
Celery	1[illegible] 000 heads	£4 to £[illegible]	1s [illegible]d per doz heads
Cucumber	[illegible] 000 from 100 ft house	£2[illegible] per house	[illegible]s per doz
Herbs (various)	1 ton (when dried)	Varies widely	[illegible]0s per cwt
Horseradish	10 000 bundles	[illegible]8s per acre	1s [illegible]d per bundle of [illegible] roots
Leeks	1[illegible] 000 bundles	£6 per acre	2s per doz bunches
Lettuce	[illegible]000 per acre	Varies greatly	6d to 1s 6d per doz
Mushrooms	1[illegible] cwt per 100 yd run	£17 per 100 yd (ridge bed)	[illegible]d per lb
Mustard and cress	This crop is grown in	many varying ways	1s per doz punnets
Onion	400 bushels	£6 10s per acre	[illegible]s [illegible]d per bushel
Parsnip	[illegible]00 bushels	70s per acre	2s 6d per bushel
Peas	1[illegible]0 bushels	Varies greatly	2s per bushel
Potatoes	[illegible] tons	[illegible]8s to [illegible]0s	£[illegible] 10s per ton
Savoy		Same as for cabbage	
Seakale	Varies greatly	Varies greatly	1s per 2 lb punnet
Spinach	4[illegible]0 bushels	As for cabbage	2s to 3s per bushel
Tomatoes	3 lb per plant	Varies greatly	3d to 4d per lb
Turnips	[illegible]00 bushels	40s per acre	4s per doz bunches
Vegetable marrow	1[illegible]00 doz	20s to 2[illegible]s per acre	1s [illegible]d per doz

rate they are liable for half the amount payable for a dwelling house but buildings thereon such as greenhouses, are liable for the full amount It may be well to state here that according to the Market Gardeners Compensation Act a market garden is "a holding wholly or partially cultivated for growing produce for market"—that is to say the crops grown on such land must be for market purposes only A private individual who has a very large garden, and disposes of certain surplus fruit and vegetables in the markets is not a market gardener within the meaning of the Act and his garden is liable to be rated at the full amount It is always well to see that the rates are properly adjusted at the commencement of the tenancy as when once a payment has been made on a higher scale it is a long and tedious process to get either a reassessment or a refund

It is, of course, impossible to lay down any hard and fast rule that will apply to the whole of the country as to the cost of maintaining a market

of some kind and the following little table gives particulars of those which are most economical

Manure	Quantity per acre	Cost
Basic slag	3 cwt	£2 per ton
Dissolved bones	[illegible] cwt	£4 10s "
Guano	1 cwt	£11 "
Nitrate of soda	1 cwt	£8 "
Sulphate of ammonia	1 cwt	£9 "
Sulphate of potash	1[illegible] cwt	£6 "

Any of these manures are suitable for market garden crops with the exception of sulphate of ammonia and nitrate of soda, neither of which is it desirable to apply to peas or beans A very cheap and effective manure for potatoes and onions is ordinary soot used at the rate of three dozen bushels per acre In the neighbourhood of a town this can usually be obtained at a few pence per bushel, rarely more than sixpence

GARDENING *concluded*

FIRE BRIGADE WORK

The Routine of the Fireman's Duties and Conditions of Work
Fire Engines and Fire Escapes   Fire Prevention Devices

from page 6723

By JOHN HENRY WHILE

THE profession of a fireman offers a wide field for activity and energy, and also affords scope for inventive genius. A young man desiring to become a fireman, a member of a trained, skilled, and well disciplined force, must start with the determination to be efficient in his work, and to study it in both theory and practice in order to be able to work all appliances which will come under his charge to the best advantage. In the following description of the training and work of firemen the procedure and system of the London Fire Brigade, as being the premier organisation of its kind in the world, have been taken as the basis upon which the subject should be studied in theory. Practical training, work, and experience are, of course, the essentials to enable a fireman to rise high in his profession.

Selection of Candidates. The system of appointing men as members of a trained fire brigade is practically the same in all large towns, the Chief Officer seeing all candidates at the principal station. In London, until quite recently, it was necessary that candidates for the appointment of firemen should be seamen, but this rule has to some extent been relaxed in recent years, although a young man fresh from the sea with clean discharge papers has a decidedly better chance of acceptance than a candidate who has been employed in more sedentary work. The men must be under thirty years of age, must measure at least 37 in. round the chest, and should be at least 5 ft. 5 in. in height. They must be men of general intelligence, and able to read and write.

The Man's "Pedigree" and Strength. The first thing the candidate is asked to do is to produce his birth certificate and his discharge papers, or testimonials as to character, service, etc. These are carefully scanned, and if they are satisfactory his height and chest measurement are taken, and he is called upon to prove his strength by raising a fire escape single-handed with the tackle reversed. The rope or fall of a fire escape tackle is 20 fathoms, or 120 ft. in length. The escape is laid on the ground rather below the horizontal position, and a tackle is attached to the carriage end of the machine and to a ring in the ground. The candidate stands on the levers of the escape, and, hauling at the tackle, has to pull the machine up from the horizontal almost to the perpendicular until the lever wheels rest upon the ground. When a man on the carriage lever is pulling up the machine with the tackle reversed, the initial pull is 240 lb., and the fixed strain when he is not pulling is 70 lb. When the machine comes to an angle of 45° the pull is 200 lb., and the fixed strain 70 lb., and this gradually diminishes until the hind wheels touch the ground.

Medical Examination. This ordeal having been satisfactorily passed, and the candidate having been approved by the Chief Officer as stout, strong, healthy looking, intelligent, and in all other respects apparently eligible, he is sent for medical examination to the surgeon appointed for the purpose. Inasmuch as service in a fire brigade requires all the energies of a man, it is imperative that only such men should be appointed as are able to pass the surgeon satisfactorily after having gone through the very severe test described. The surgeon, as he thinks fit, either rejects or passes the man, in each case giving a certificate. The certificate given in the case of an approved man takes the following form: "This is to certify that I have examined A. B., and believe him to be free from disease and well suited for the situation of a fireman in the London Fire Brigade."

Probation. These preliminaries settled, the candidate becomes a probationary fireman, and is drafted into the drill class among other men undergoing instruction. In London his course of instruction is carried out at the fine headquarters at Winchester House, Southwark Bridge Road, where he lives for the first three months of his life as a fireman.

A Fireman's Kit. The first morning after the candidate joins he is introduced to his future companions of the drill class, and receives his kit. This consists of three pairs of top boots for fire purposes, three pairs of trousers, three cloth tunics, two jumpers for light wear, three caps, a helmet, belt, axe, spanner, and a pair of shoes for gymnasium purposes. He is found quarters in the drill class block, and messes with his future comrades. He is supplied with a mattress, palliasse, three blankets, and a pillow, but has to find his own sheets and pillow slips. His drill commences from the first day he joins, and he has to complete three months in the drill class from the time of joining. If it is necessary to send him to an out-station before the time has elapsed, he has to return to Southwark and complete the period of drill.

Syllabus of Drill. The drill class of the London Fire Brigade is split up into two parts, the theoretical and the practical sections. For both sections there are two syllabuses of instruction, which are worked in alternate weeks in order to make some change in the routine. The men under instruction, it should be said, are under two instructors, with a station officer in charge. In all cases the bells are rung at a quarter to seven o'clock, and the day's work is opened by physical exercise with Indian clubs and fire ladders. An hour is devoted to cleaning the dormitories, etc. From eight o'clock until nine the men are engaged in breakfast, bed making, and so on, and from nine o'clock to half past nine in cleaning the appliances. There is a stand easy from 9.30 to 9.45, and then the actual work of the day commences.

Theoretical Instruction. The syllabus of work for the theoretical section may be set out in detail day by day. It is as follows:

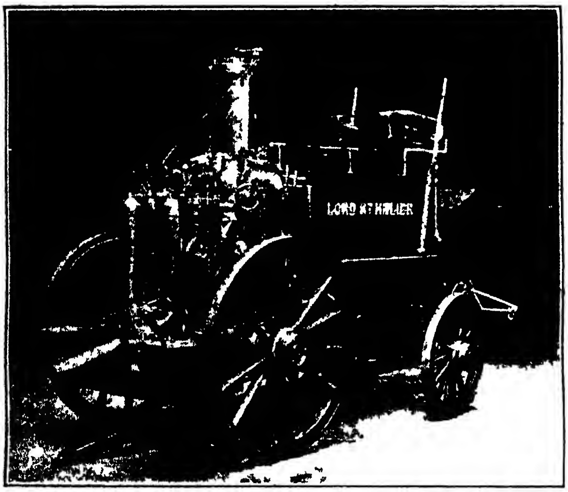
Monday. The men are lectured for three quarters of an hour on the organisation of the brigade and the duties of a fireman. The clothing and general surroundings of the watch room are inspected. An explanation of the nature and use of the helmet, axe, spanner, and gear generally is given, and the instructor adds hints as to the mending and general care of the London County Council clothing. Two

hours are allowed for dinner. In the afternoon, the instructor gives a general explanation of all gear carried on the engines, the method of stowing it, and the different screws and couplings used in the brigade.

Tuesday After physical drill, the instructor gives lecture No 2, on the mobilisation of the brigade, and the systems of fire alarms and communication by telephone and electric bells He also deals with the use of long and short lines knotting, hitches etc, and explains methods of rescue by means of lines In the afternoon instruction is given on London water supply mains service pipes supply pipes fire plugs cocks and hydrants the men receiving a thorough insight into the way in which London is supplied with water for fire purposes

Wednesday After the usual drill the members of the theoretical class assist to prepare for the general display which is always given to the public at the Southwark headquarters on Wednesdays and are instructed in jumping into sheets and in methods of rescue work with lines In the afternoon they assist with the general drill

Thursdays The instructor delivers lecture No 3



1 300 GALLONS EXPANSION STEAMER
(Shand Mason & Co Ltd)

on fires, methods of dealing with chimney fires and the use of large and small canvas dams at fires In the afternoon the men are instructed in the use of first aid appliances and receive an explanation of the methods of using branches nozzles hose suctions, and couplings together with a description of the manufacture and method of making up lines of hose

Friday After physical drill the men are instructed in bringing down insensible persons and in the use of the smoke helmet In the afternoon they take part in wet drill with a steamer and in the evening clean out all the dormitories

Saturday After the general work of assisting in cleaning all gear and the headquarters generally, the men 'stand easy'

Alternative Syllabus. The alternative syllabus of the theoretical class, which is carried into effect on the second and fourth weeks in each month, includes the usual routine of physical drill every morning. On *Mondays* the men receive instruction in picking up and bringing down insensible persons, and take part in bucket, hand-pump, and manual drill. In the afternoons, they carry out scaling and hook ladder drill, and receive explanations of the fire alarm system, and of the proper methods of forwarding 'calls,' 'stops,' etc, in regard to actual fires

On *Tuesdays* they enter upon hose cart drill with hydrants and stand pipes and in the afternoon take part in horse escape drill, and in exercise rescue work

On *Wednesdays* the work is practically the same as that given under Theoretical Instruction

On *Thursdays* the men receive an explanation of the use of the manual engine and of first aid appliances and undergo in the afternoon watch-room instruction and an explanation of the methods of carrying out duties and watches at street stations and in fire escape boxes

On *Fridays* they are drilled in the work of carrying down insensible persons restoring life by artificial methods and in escape work Friday afternoons are devoted to general cleaning up work

The Practical Class. From the theoretical class the novices under instruction are promoted to the practical class where the early morning routine is the same The first week's syllabus of instruction apart from this routine consists briefly stated, of the following programme of work

Monday The men are instructed in the method of picking up insensible persons they prepare for and carry out wet drill with a steamer In the afternoon they receive instruction in testing and repairing hose undergo practice in rendering first aid to the injured drill with the horsed escape are instructed in the use of escapes and ladders in cases of emergency, and carry on rescue work with lines They pack up at four o'clock The men are divided into three watches of leave, and those on leave are at liberty until 1 a m, while the others engage in station and other duty

Tuesday The members of the practical class are exercised with jumping sheets and in hose cart drill in addition to horsed escape and manual drill In the afternoon they are instructed in the geography of the London County Council area, the mobilisation of the Brigade and the duties of firemen generally

Wednesday The curriculum includes much of the previous drill and also extends to the use of smoke helmets scaling ladders as used in climbing over walls and roofs at actual fires hand pump drill rescue by lines long ladder drill, and preparations for the general drill The men construct large canvas dams in the drill yard and fill them for the purposes of the public drill

Thursday The same drill with variations, is carried out and in the afternoon all appliances are washed off, tested, oiled and cleaned generally

Friday The men receive instruction in the stables harnessing horses, and are taught to assist the coachmen in getting them away quickly Later on they practice carrying insensible people off the roof, and take part in smoke helmet and hose cart drill combined All dormitories are cleaned out in the evening, and on all Tuesday and Friday nights ambulance classes are carried out

Practical Class. The alternative syllabus for the practical classes includes, on Mondays, a lecture on the duties of firemen in regard to calls to fires and chimney fires, and to the methods of work

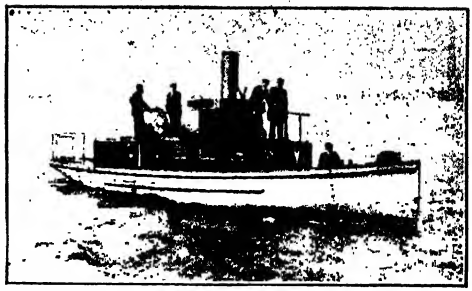
at actual fires. In the afternoon, the ladders and lines used in the Brigade are tested, and wet drills with a steamer and horsed escape, manual, and scaling ladder drills, are carried out. On Tuesdays, the curriculum includes horsed escape, hose-cart, and escape drill, the use of first aid appliances, and instruction in the organisation of the Brigade, watch-room routine, and the methods of keeping an "occurrence book." On Wednesday, the ordinary routine of the public drill day is carried out. On Thursdays, the chief duty is to test, wash, and clean all appliances, while on Fridays the work includes physical drill, instruction in stables, practice in carrying down insensible persons, hook-ladder and escape drill, and wet drill with the steamer. The bedrooms and mess-rooms are scrubbed out, and at night the ambulance class is held.

When a period of three months of this arduous and continuous drill has been carried out, the men are rightly considered to have become proficient in their new calling, and, as vacancies occur, are drafted out to different stations in various districts of London.

Duties of Firemen. The general duties of a fireman are to reside at the station to which he is appointed, to be at all times within hail, and available for any duty, unless specially booked otherwise; to take his turn in watching at the station, taking charge of escapes, attending fires, and all other duties, when ordered by his superiors; to assist in the cleaning and other work at the station, relieving the men on duty for meals, etc; to be civil and respectful in his demeanour, and clean in appearance; to perform all duties entrusted to him in a prompt and efficient manner; to hold himself in readiness for any duty he may be called upon by his superiors to perform; to obey implicitly all orders of his superiors, and to exact the strictest obedience and respect from those under him; to study and otherwise endeavour to qualify himself to perform the duties of his superiors when called upon to do so.

Special Duties. There are four distinct classes of firemen, apart from officers—namely, first, second, third, and fourth—and the above duties, as general rules, apply equally to them all. It happens, however, that in the carrying out of the laborious work of a fire brigade, there are many duties requiring special qualifications and capacities, and these naturally fall in most cases to the lot of those who have served longest and worked hardest. These duties consist of taking charge of the floating steam-engines and the land steam-engines, mechanical work at the factory, repairing engines, and so forth, drilling and instructing the young hands, keeping the accounts, books, and records of the establishment, and preparing reports, etc. It is therefore incumbent on all ranks to study and understand, not only their ordinary duties, but also those of their superiors, in order that, when called upon, they may be found equal to the performance of any duty devolving upon them.

General Working. Every man is always supposed to be on duty, for duty, on leave, sick, or suspended. Those on duty are in full dress, with the exception of their helmets. Those for duty are ready to turn out at a moment's notice, and are therefore not permitted to go outside the station, except within view. An officer in charge of the station has power to grant leave to any man of his own station up to eight hours; a Superintendent has power to grant leave up to 48 hours; and any leave which exceeds 48 hours must be granted by the Chief Officer.



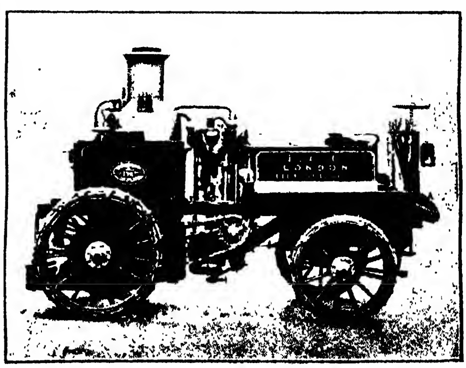
2. RIVER FIRE FLOAT
(Armstrong, Whitworth & Co., Ltd.)

When the men under instruction are drafted out, as already described, they are classified as fourth-class firemen, and remain in that position for three years. At the expiration of that time, on the recommendation of their officer, they are promoted to the rank of third-class firemen. After that, promotion is by merit, as proved after examination.

Steam Class Drill. In due course, the third-class fireman returns to headquarters to undergo a course in steam drill, which will enable him to take charge of a steam fire-engine. Later on, if he succeeds in passing an educational examination, he rises to the rank of second-class fireman, every promotion carrying with it increased pay. Promotion to the first class is obtained by the passing of a special examination, which includes writing, arithmetic, the making up a pay-sheet, the geography of the Brigade, and such miscellaneous subjects as may be selected by the education board, which is drawn from the officers of the force.

Higher Promotion. As time goes on, and vacancies occur, men passing special examinations become sub-officers, and at the end of 15 years of completed service a fireman in the ranks has a fair chance of becoming a station officer, and of taking charge of one of the fire stations which are scattered all over the metropolis. The next rank is that of District Officer, and finally a member of the London Fire Brigade has a chance of rising to the status of Superintendent, and of taking charge of one of the six districts into which London is divided for fire brigade purposes.

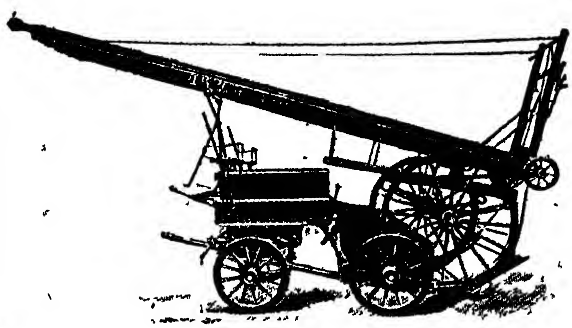
Fire-engines and their Management. The plant with which a fire brigade has to deal naturally varies in extent, according to the size of the city or town which it has to protect. In London the appliances used are of a very varied



3. MOTOR "FIRE KING" (Merryweather)

character in order to suit the different localities which have to be protected, the City and Central London districts requiring more powerful appliances and longer fire ladders than are requisite for service in suburban districts. The plant may be summarised as consisting of hose-carts, manual engines, steam fire-engines [1], motor fire-engines [3], horsed escapes for life-saving purposes, extension ladders for fire extinguishing purposes, chemical first-aid appliances (now carried on all horsed escapes), hose, coal, and oil vans, fire-engines on barges, and a river float [2] for dealing with riverside fires. Fire-engines, it may be briefly said, are of various kinds. Some are fixed in walls or stationary places, and cannot be moved at all, some are fixed in ships or barges on the water, and others in carriages on land; some are in themselves movable, and, whether on fixed or movable foundations, can be mounted or dismounted at pleasure. Some are worked by water, some by steam, some by manual power, and some by chemicals.

Hose-carts. A hose cart is a light box built on a pair of wheels to carry three 100-ft lengths of hose, without the inconvenient addition of a reel. The box has a capacity of 13 cubic ft, of which 10 cubic ft. are for the hose and three for the tools. The hose can be laid out from a hose-cart as from a reel, and when not in use is protected from the weather and kept quite clean. A hose-cart, when empty, weighs $2\frac{1}{2}$ cwt., and when full, $5\frac{1}{2}$ cwt. and it can easily be run to a fire by one man.



4 HORSED HOSE AND LADDER TRUCK
(Bayleys, Ltd)

A Six-inch Manual Fire-engine. Although manual engines have gone out of vogue in London, they are still extant in certain local districts of the metropolis, and a great number are in use by brigades all over the United Kingdom. A 6-in. manual consists of a pair of single acting force pumps, with an inlet pipe, four valves, an air vessel, two delivery pipes, and a rocking shaft, mounted on a carriage with four wheels, and worked by levers, which are attached to a spindle passing through bearings in the carriage frame. It is, therefore, so far a fixture that the pumps cannot be separated from the carriage without delay and difficulty, but the whole machine, including the travelling and working parts, is movable, and is made as light and portable as is consistent with the necessary strength.

The sole-plate, on which the works are fixed, is a box or bed of cast iron, comprising the bottom, sides, and part of the top of two pairs of valve-boxes, one pair behind and one in front, flanges to receive the corresponding flanges of the cylinders, and the bottom and sides of two waterways, one at each side. The waterways begin at the hind or stern end of the valve-box, where they are separated and pass forward, each through one part of the hind valve-box, underneath the cylinder at the same side, and through the front valve-box, in front of which they come together again, thus forming two curved channels, starting from the same point behind, and joining again in front. The suction-valves, two in number, are made of gunmetal, and are of the kind commonly known as hinged inclined metallic valves. These valves are self-acting—that is, they are not fastened by means of connecting rods or otherwise to any of the moving parts, and consequently are not set in motion by any direct action of machinery, as is the case with mechanical valves, but are opened by the fluid, whether air, water, or other substance, which is passed through the pump, and when this pressure ceases, close of their own accord by gravitation. The lift of these valves is $1\frac{1}{4}$ in., and the area of the opening is 4.9 sq. in. The force necessary to open them is a pressure of ·254 lb., or, in round numbers, about $\frac{1}{4}$ lb. on the square inch.

The engine has a pair of cylinders on opposite sides of a rocking shaft, with pistons driven by a reciprocating movement of the arms of the working beam. The united capacity of the two pumps, or the quantity of water received and discharged on a stroke of the engine is 452.38 cubic in., or 1.63 gal. In round numbers, the capacity of the engine is a little over $1\frac{1}{2}$ gal. When the engine is in proper order, and worked at reasonable speed, the quantities of water delivered are in exact proportion to the number of strokes made, without reference to the force applied, the speed at which the handles are worked, the pressure, or any other circumstance. The engine can be worked to the best advantage by thirty men, and the harder they work the greater will be the result but the quantities of water delivered are measured not by the amount of their labour, but by the actual result made good in the number of strokes. The proper crew for this engine consists of four firemen and a coachman, and their weight in full uniform may be taken at an average of about $7\frac{1}{2}$ cwt. The total weight of this engine when proceeding to a fire may be estimated as follows: engine, 18 cwt., gear, $6\frac{1}{2}$ cwt., men, $7\frac{1}{2}$ cwt.; total, 32 cwt., or, in round numbers, between $1\frac{1}{2}$ tons and $1\frac{3}{4}$ tons.

Steam Fire-engines. The fire brigade experts of London and other great towns have found that the best steam-worked pumps, or steam fire-engines, are those which are of simple construction, the parts of which are the most visible and accessible, and it is hardly necessary to point out that in principle there is no difference in the action of a pump, whether the motive-power be produced by men, by water, by steam, or in any other way. Pumps driven by steam are, in practice, run faster than those driven by hand power, and consequently the valves are generally arranged to work more quickly. For the sake of silence, as well as to avoid the risk arising from constant blows, they are generally made either of some soft material or of metal mounted with a soft facing of leather or rubber. Occasionally absurd powers are attributed to steam fire-engines by ignorant or interested

persons, and in that respect it is necessary only to say that the real capacities of the machine can be tested by any engineer in the ordinary way by having their horse power indicated, and that the equivalent man power can be obtained by multiplying the horse power by 5. Where steam fire engines are used there is a choice of only two courses with respect to their getting to work. One is to wait fourteen minutes while raising steam, and the other is to keep the water boiling in the engine house, so that the steamer, when called out, will have a sufficient working pressure of steam in about three minutes.

Manipulating the Fire-engine. Every boiler of the pattern at present in use is fitted with a glass water gauge of which the bottom cock is on a level with the upper tube plate or crown of the fire box, and the top cock 12 in. higher. The glass is protected by guard brasses fastened at the top and bottom with sheet brass clamps, and the guards are marked so as to show the inches above the crown plate. There are 7½ in. of the glass visible between the clamps. Each boiler has three gauge cocks, the bottom one being 2 in. above the crown plate, the middle one 3 in. above the bottom, or 5 in. above the crown plate, and the upper 3 in. above the middle, or 8 in. above the crown plate. The bottom gauge cock should always show water, the top gauge cock should always show steam, and the middle gauge cock should generally show both water and steam.

Steam duties on board the floating engines[2] and in charge of the land steamers comprise work which requires a large amount of special explanation, which is given by responsible officers, and can be understood only after long study and explanation. No man receives a charge of this kind until he has first proved his professional qualifications for it. The general instructions issued in the London Fire Brigade for working a land steam fire engine, it may be stated, include the following.

1. The boiler of this engine is to be worked at a pressure not exceeding 120 lb. on the square inch.

2. The safety valve is not to be screwed down to more than 100 lb., and the engineer must occasionally raise it by hand or otherwise both when getting up steam and when at work.

3. In order to keep this valve free, and to prevent it sticking, he is to ease up the spring, and to remove the whole pressure from it when not required, except sufficient to keep the lever and spring balance from shaking while the engine is travelling.

(4) Whenever the work admits of it the engineer is occasionally to fill his boiler with water as high as possible without allowing it to prime, and then blow off from all the cocks, including the gauge cocks, using only one at a time. This is the best precaution against scale or scum, and an intelligent engineer will find many opportunities of adopting it without interfering with the necessary work of his engine.

(5) In addition to this, the boiler is to be altogether blown out, and washed out occasionally.

(6) The engineer must be careful to see that no soot is allowed to accumulate on the shelf or tube plates of the boiler, as this would reduce its steaming power considerably.

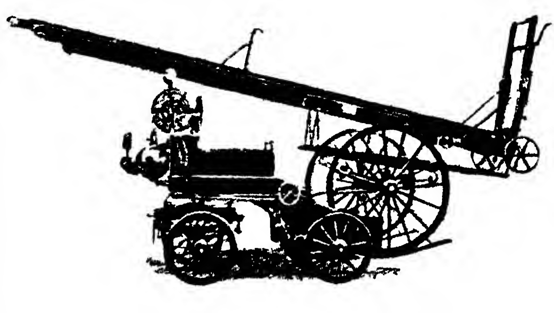
(7) The engineer is held responsible that the water in the boiler is always kept in sight in the gauge glass, whenever the fire is alight, and in case of any accident such as the failure of the feeding apparatus, rendering this impossible, he is immediately to draw his fire.

(8) A sufficient quantity of water should always be kept in the feed vessel for supplying the boiler when the engine is not at work.

(9) It being exceedingly dangerous to pour cold water on hot boiler plate, the engineer is desired to be particularly cautious about putting cold water into the fire box, and in case it becomes absolutely necessary to do so he is to pour it on the fire bars only, and not on the inner shell of the boiler or the tube plates.

(10) After the suction pipe has been taken out of the water the engine should be run round for a few strokes in order to blow the remaining water out of the pump.

(11) On his return from a fire the engineer is to enter in the book kept for that purpose the following particulars as far as he is able—namely, time at work, number of revolutions, quantity of water delivered, and any other circumstances which appear worthy of remark, such as the length of hose, number of deliveries, height of branch above engine, etc.



5. CHEMICAL EXTENSION LADDER

Hose. The laying out and handling of the flexible pipes or hose which convey water have much to do with the most active part of a fireman's work. The pipes are chiefly of two kinds, the one known as suction pipes, which convey the water from the reservoir or hydrant to the pumps, the other delivery pipes, or hose which convey the water from the pumps to the fire.

Suction pipes are made of leather stretched over a metal spiral, which prevents them from collapsing when a vacuum is formed inside. Suction pipes are of three sizes, and are carried on the engines in short pieces. They are mounted with couplings of an exactly uniform pattern, and can be used singly or with several joined together according to their respective size.

Delivery pipes or hose are made of canvas or leather. The hose at present almost exclusively used by the London Fire Brigade is of canvas, and is for the most part lined with indiarubber. The canvas pipe is made of the best flax, carefully woven, with about 10 turns to the inch in the weft or circular thread, and about 15 threads to the inch in the warp or longitudinal thread. A length of canvas seamless rubber lined hose as delivered by the various manufacturers for the use of the London Fire Brigade, has an internal diameter of 2¾ in., so as to take a coupling with a 2 in. waterway, and is almost invariably 100 ft. in length. Each length of hose is provided with a leather strap, 3 ft. 3 in. long and

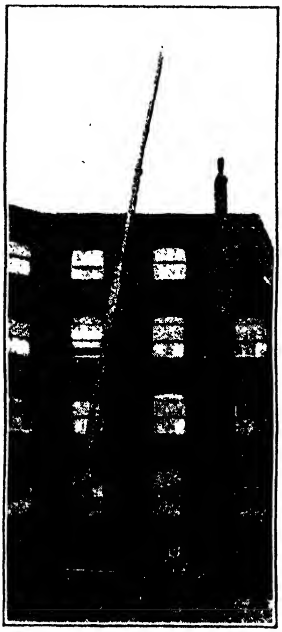
1¼ in. wide, fitted with a suitable tinned-iron roller buckle, riveted to it, and a collar to slide along the hose. The rivets and washers are of the best wrought copper, properly tinned to prevent verdigris.

Chemical Engines, or "First Aid" Appliances. The chemical engine consists of a copper cylinder holding 24 gallons of water. This is connected to a compressed air cylinder by a copper tube fitted with a suitable valve. The compressed air, on being admitted to the copper cylinder, drives the water out through an indiarubber hose which terminates in a stopcock jet. The hose is wound round a reel, and the water enters it from the centre of the reel, so that any length can be run out, and no connecting up is required. A length of 50 ft. of 1 in. hose is usually supplied, and it is carried already filled with water.

The copper cylinder is fitted with a safety valve and pressure gauge, so that the screw-down valve which lets in the compressed air can be opened or closed to the correct extent. On arrival at the fire a man takes the jet in his hand and runs with it to the seat of the fire, the hose winding off the reel as he runs. The valve is open and the compressed air is let in. All the man has to do on reaching the fire is to turn on the stopcock of the jet. He then has a powerful jet of water which will carry 50 ft. to 60 ft., and which flows for about eight minutes.

Should a further flow be required, there is a connection fitted to the copper cylinder to take the standard 2½ in. coupling, so that the water from the main can be brought through the indiarubber hose.

Fire-escapes. Fire-escapes are of various sizes and patterns, and differ considerably in certain small matters of arrangement of parts, and so forth, but the best of those in use are for the most part similar in all the essential points. An ordinary fire-escape is a ladder mounted on a carriage with four wheels, two high and two low. When all the wheels are on the ground the escape stands at an angle of about 25° from the perpendicular, and would fall over unless supported by being pitched against a wall, or balanced by a pressure at the end of the folding lever attached to the carriage. The general dimensions on an ordinary hand fire-escape are as follows: main ladder, 50 ft. 3 in.; fly ladder, 19 ft. 4 in.; first-floor ladder, 16 ft. 3 in.; supplementary ladder, 10 ft. 4 in. The modern appliance, now in use in London, is the horsed escape [4], and in this case the escape is carried on a van, which is drawn by two horses, and is turned out from the station and galloped to the scene on the first ringing of any fire alarm signal into the depôt. In the case of these escapes, the ladders are to a certain extent telescopic, and they are supplemented by hook ladders, with which the men mount from window to window for rescue work. They also carry hose.



6. 70-FT. TURNTABLE FIRE LADDER
(Shand, Mason & Co., Ltd.)

A fire-escape when properly pitched may safely carry a man on almost every round, and a fly ladder, when unshipped and standing on the ground, may carry some eight or ten men; but a fly ladder when thrown, ought not to have more than about three men on it at a time, as the whole weight comes on a single spot of the main ladder. In all ladders it is necessary that great care should be taken to distribute the weight, and not to allow it to rest on one spot or one portion. Thus, for instance, a ladder 28 ft. long may carry one man on every round, or 28 men in all, whereas six men at some one spot may instantly break it.

Firemen must always use the greatest discretion in leaving their escapes, even for a moment. There are cases in which a fireman is justified in running away with a hand pump, or one of the small ladders, as, for instance, when a fire is discovered within a few feet of his post and within sight, but even under these circumstances he ought to be very cautious.

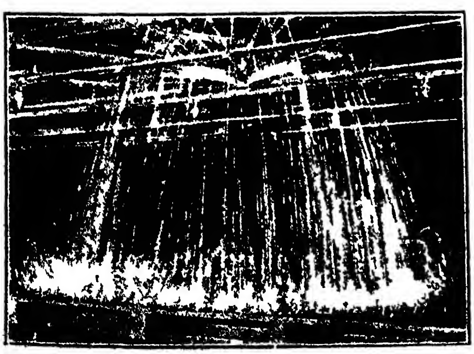
Life Saving. The all-important work of saving life from fire includes many and various branches. If all houses were exactly alike, with the same contents, the same number of inmates, and those all of the same ages, the same conditions of activity or helplessness, and occupying the same parts of the houses, it might be possible to lay down precise rules for their rescue; but when it is remembered not only that the circumstances are never alike in any two cases, but that the time of the "call" being sent away from the house on fire, the time of its being received at the escape station, and the time of the arrival of the escape all depend upon a number of contingencies which differ most materially, and can never in any way be foreseen, it will at once be obvious that in almost all cases everything depends on the quickness, presence of mind, and personal activity of the fireman in charge. To do his work properly, a fireman must be strong, quick, fearless, and intelligent; but above all things, he must be resolute.

Extension Ladders. For purposes of dealing with fires in lofty warehouses, extending ladders on a telescopic principle are largely used in the London Fire Brigade, and the most up-to-date appliance is a ladder which extends itself automatically by the force of chemicals [5]. In the ordinary long ladders the appliances are usually extended by means of a screw-handle. Turntable ladders are also used by the Brigade [6].

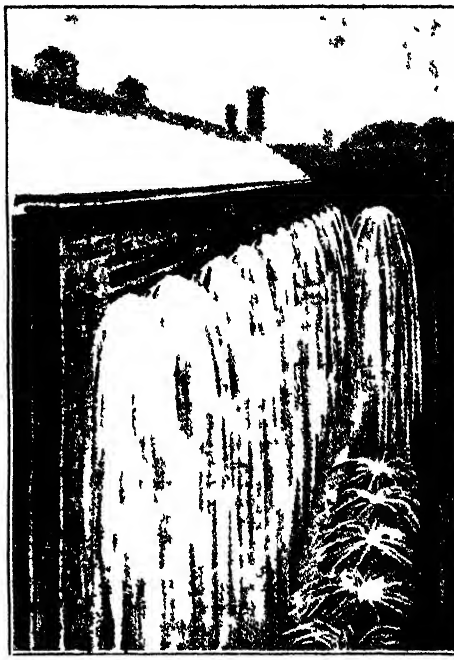
The Actual Work of the Brigade. The manner in which the London Fire Brigade deals with actual fires depends, naturally, upon the character and extent of the outbreak. There are three ways in which the firemen receive "calls" to fires—either verbally from civilians or policemen, by the ringing of fire-alarm signals, or by messages over the telephone through the Telephone Exchange. In any case, the station which receives the first "call" responds by sending out, first, a horsed escape, and then a steamer. The particulars of the first "call" are instantly telephoned by the duty-man, who remains at the station, to the district headquarters, and from that centre the firemen at the other stations nearest to the fire are ordered to proceed with their steamers and other appliances.

Early Work at the Fire. The first arrivals at the fire immediately proceed with the task of extinction and rescue work, if there be any necessary, and upon the officer in charge devolves the responsibility of communicating immediately to his district headquarters a message describing the character of the outbreak. This is done from the nearest fire alarm post by telephone, for practically all the fire alarm posts in London are now telephone stations as well. There are three code messages which are used, and which indicate whether the fire is a slight fire, a serious fire or a very dangerous fire. If the outbreak is one which can be dealt with by the appliances in hand the words "home call" are telephoned to the district depot, and no more appliances are sent on. Should the fire be a serious one, and spreading, the message "district call" is transmitted and altogether a force of about seventy firemen, a dozen steamers, long ladders, and other appliances are despatched from the different fire stations in the particular district in which the fire is raging. The superintendent of the district proceeds to the scene to direct operations, and every steamer, as it arrives with full steam up, begins to pump water on the burning building. In the event of the fire being a very serious one, the message "brigade call" for the particular locality in which the conflagration is raging is telephoned to the Southwark headquarters, and then every district in London is called upon to render assistance. A score of steamers are hastily concentrated at the scene, the river floats are ordered to proceed from their moorings if the fire is anywhere near the river side, huge canvas dams are erected for the engines to pump water from, and within a marvellously short space of time powerful land steamers will be busy in every street surrounding the property involved throwing thousands upon thousands of gallons of water upon the flames. The efforts of the Brigade will probably be directed by the Chief Officer and his three Divisional Officers, assisted by the Superintendent of the district, and while the fire continues to rage coal and oil vans will be continuously running between the scene of the fire and the local headquarters carrying fuel for the steamers, some of which now work with petrol. When the fire is "in hand" a message is despatched giving the code word "stop" and stating that no more help is required, while later on a brief summary message as to the extent of the damage is forwarded to headquarters.

Outside Fire Appliances. Apart from the different devices and appliances which the London



8. SPRINKLERS INSIDE A BUILDING



7. SPRINKLERS IN ACTION OUTSIDE A BUILDING
(Mather & Platt Ltd.)

Brigade uses in its work of coping with fire are many useful inventions of which large private firms avail themselves for the purpose of disclosing automatically an outbreak of fire and of checking it in its incipient stages. These devices include automatic fire alarms which are arranged so that when the temperature of a room, office, or warehouse floor rises to a certain degree a melting takes place, the immediate result of which is to ring alarm bells outside the building, or in connection with one system into the central office some distance away, from which the fire alarm is given to the fire brigade.

Automatic sprinklers are arranged on a similar system, and when the temperature rises to a certain degree in a room or office in which the sprinklers are fitted a wax connection is melted which releases a force of water from fitted pipes. The water in its turn acts upon a sprinkler, and the goods beneath this arrangement are presently deluged with water [8]. At least one large building in the City is fitted with a system of sprinklers [7] which, when in operation, makes a complete curtain of water outside the building and on every side of it, the idea being that should a fire break out in an adjoining warehouse the sprinklers could be set to work and would act as a shield to the warehouse in which the device is fitted.

Progress and Improvement. In every branch of fire brigade work there is so much scope for improvement that it would be a wise man who could prophesy when finality will be reached, and in view of the remarkable advance which has been made even in the last decade in fire extinguishing and life saving appliances, it seems safe to prognosticate that every year will witness further developments and improvements in these all important devices.

FIRE EXTINCTION *concluded*

COMMERCIAL & PERSONAL LAW

Commercial Law—continued. Employers' Liability. Landlord and Tenant. Personal Law. Marriage and Divorce. The Married Woman's Property Act

THERE remains to be given briefly the rules as to delivery, which will be found in Sect. 29, 32, and 34 of the Sale of Goods Act.

Sect. 29.—(1) *Whether it is for the buyer to take possession of the goods or for the seller to send them to the buyer is a question depending in each case on the contract, expressed or implied, between the parties. Apart from any such contract, expressed or implied, the place of delivery is the seller's place of business, if he have one, and if not, his residence, provided that, if the contract be for the sale of specific goods which to the knowledge of the parties when the contract is made are in some other place, then that place is the place of delivery.*

(2) *Where under the contract of sale the seller is bound to send the goods to the buyer, but no time for sending them is fixed, the seller is bound to send them within a reasonable time.*

(3) *Where the goods at the time of sale are in possession of a third person, there is no delivery by seller to buyer unless and until such third person acknowledges to the buyer that he holds the goods on his behalf, provided that nothing in this section shall affect the operation of the issue or transfer of any document of title to goods.*

(4) *Demand or tender of delivery may be treated as ineffectual unless made at a reasonable hour. What is a reasonable hour is a question of fact.*

(5) *Unless otherwise agreed, expenses of and incidental to putting the goods into a deliverable state must be borne by the seller.*

Sect. 32.—(1) *Where, in pursuance of a contract of sale, the seller is authorised or required to send the goods to the buyer, delivery of the goods to a carrier, whether named by the buyer or not, for the purpose of transmission to the buyer, is prima facie deemed to be a delivery of the goods to the buyer.*

(2) *Unless otherwise authorised by the buyer, the seller must make such contract with the carrier on behalf of the buyer as may be reasonable, having regard to the nature of the goods and the other circumstances of the case. If the seller omits so to do, and the goods are lost or damaged in course of transit, the buyer may decline to treat the delivery to the carrier as a delivery to himself, or may hold the seller responsible in damages.*

(3) *Unless otherwise agreed, where goods are sent by the seller to the buyer by a route involving sea transit under circumstances in which it is usual to insure, the seller must give such notice to the buyer as may enable him to insure them during their sea transit, and if the seller fails to do so, the goods shall be deemed to be at his risk during such sea transit.*

Sect. 34.—(2) *Unless otherwise agreed, when the seller tenders delivery of goods to the buyer, he is bound on request to afford the buyer a reasonable opportunity of examining the goods for the purpose of ascertaining whether they are in conformity with the contract.*

Acceptance. And lastly there is the law to *Acceptance:*

Sect. 35.—*The buyer is deemed to have accepted the goods when he intimates to the seller that he has accepted them, or when the goods have been delivered to him, and he does any act in relation to them which is inconsistent with the ownership of the seller, or when, after the lapse of a reasonable time, he retains the goods without intimating to the seller that he has rejected them.*

Sect. 36.—*Unless otherwise agreed, where goods are delivered to the buyer, and he refuses to accept them, having the right so to do, he is not bound to return them to the seller, but it is sufficient if he intimates to the seller that he refuses to accept them.*

We have endeavoured to give the simple rules which the business man should master in the daily course of his affairs. To discuss such matters as stoppage in transition, lien, "rights in rem" and in "personam" would be profitless here, since they correlate some basis of legal training.

Agency. It is still necessary to give a few rules explicatory of the doctrine of *Agency*, and then we can pass on briefly to other parts of the law which deals with a man in his life in the world.

The great distinction in *agency* lies between the agent proper, or particular, and the broker or what we might call the agent general. The agent proper is the nominee of any individual business man to do his business, to sign for him in any particular transaction or series of transactions. Such an agent is in a semi-fiduciary position towards his principal; he may be paid by salary or commission, and face to face with the other side in the transaction he practically *is* his principal. What the latter does through him he does himself. The principal is liable for the agent's negligence or tort or (to a certain extent) dishonesty.

A broker, on the other hand, is a person whose business it is to carry through contracts of sale and purchase of goods which are not his and which he does not buy for himself. He may be the agent both of the vendor and the vendee—indeed usually is. His responsibility to either is not in any way so onerous as though he were the appointed private agent of either. The niceties of the law upon this subject are great, but the business man may content himself with this single broad distinction.

He should realise in all cases where he is interested in transactions carried through by delegated authority whether the delegated authority is that of a private agent of his own or of a general agent or broker. And in the same way the agent should be clear in his own mind whether he is employed by one principal or by more than one. The difference is of vital importance to his status, and to what he can and cannot do. With that broad distinction we must leave the law of sale and purchase and pass on to the next branch of a man's daily life.

The Law of Service. Since every human being of adult years is either a servant or a master, and not infrequently both, it stands to reason that the laws governing employment must be of vital importance to very many. In even the simplest cases questions arise as to how wages should be paid, when are they due, what notice should be given, and the like.

At the outset let it be said at once that a great deal of nonsense has found its way into the heads of ignorant people upon these subjects They imagine that the law will not allow this or will allow that, whatever the arrangement between the individuals Let it be said at once that the policy of our law is to leave as free a hand to individual idiosyncrasies as possible So long as an agreement is not immoral or against public policy or obviously oppressive or obtained by misrepresentation or fraud or duress the law will compel its fulfilment

If A and B agree to become master and servant respectively, with wages paid at uncertain intervals and no notice of termination on either side that is a perfectly good agreement and can be enforced As a rule, however, parties do not care to enter upon eccentric arrangements of this kind Very often in domestic service no written agreements are drawn up, since none are required and then it becomes a matter of interest to state what implied rules of law govern these relations In English domestic service the usage is that in the absence of any express agreement, the wages should be paid monthly and that the service should be terminated by a month's notice on either side In lieu of this a month's wages must be paid or forfeited Of course, gross insubordination upon the part of the servant or drunkenness or immorality or culpable and wilful carelessness justifies the employer to dismiss without any notice and in the same way a servant who is badly treated or starved may leave at once without notice All these points are matter of fact or proof

Summary Dismissal. The cause for summary termination must be a substantial one Carelessness on the part of the servant or unsuitability on the part of the employer would not justify it The wages need not be paid in advance unless there is an agreement to that end But they must be paid when due The employer may make deductions from them for breakages but such deductions must be honest and careful and not capricious The employer is bound to feed his indoor domestic servants and give them proper sleeping accommodation—though there is no real supervision to ensure either of these requirements and in London at any rate, even in the best houses they are often conspicuous by their absence The servant is entitled to reasonable relaxation No employer is entitled to turn a servant into a slave And this relaxation must include leave of absence at stated intervals Every servant has a right to that, and where it is denied the servant is entitled to leave forthwith, and no court in the country would think for a minute of penalising such conduct

If a servant is insubordinate an employer may turn him (or her) out, but the employer will not escape responsibility for any breach of the peace that may ensue If an employer has reason to believe that a servant has secreted some of his property he is not entitled to search the servant's boxes without an order from a magistrate and in any case an employer is never allowed to detain a servant's luggage It may be added that even in cases of summary dismissal a servant is entitled to recover arrears of wages but of course only those accruing, and not any compensation in lieu of notice Domestic servants are now entitled to compensation for injuries, but this does not deprive them of their common law right to recover damages against their employer for culpable negligence resulting in disablement.

Clerks and Workmen. Employees who are not menials—*e g.*, clerks, staffs of banks, etc., governesses and tutors—are usually, in the absence of agreement to the contrary, entitled to a quarter's notice In this respect the usage of any particular calling may have weight with the court provided it can be proved Agreements for employment where the employee agrees not to follow out the same business himself in the same area after leaving are good in law But an agreement not to follow the same business at all anywhere would probably be bad

Workmen come under a class by themselves, and may be defined thus

Workman does not include a domestic or menial servant but means any other person who being a labourer servant in husbandry journeyman, artificer handicraft man miner, or otherwise engaged in manual labour whether under or over twenty one years of age has entered into or works under a contract with an employer whether the contract is made before or after the passing of the Act (38 and 39 Vict cap 90) be expressed or implied oral or in writing and be a contract of service or a contract personally to execute any work or labour

The Truck Acts. The Acts known as the 'Truck Acts' which are now being altered and recodified are directed to a very simple principle Their object is to prevent masters paying their workmen in kind or making deductions from their wages The Truck Act of 1831 forbids the payment of wages in aught but the current coin of the realm No stipulation must be made by the master as to where and when the wages may be spent or how No employer may pay wages in goods nor can he set off against a claim for wages goods supplied by the employer, or supplied by any shop in which he may have an interest Infraction of the provisions of this Act lays the employer open to a heavy fine

In 1887 the former Truck Act which still remains in principle the law of the land was greatly extended, and to a certain extent it was modified Thus, the new Act specifically recognised a contract with a servant in husbandry for giving him food, drink (non intoxicating) a cottage or other allowances *in addition to* money wages as part payment for his services

It is expressly enacted that no employer shall dismiss any workman from his employment because he spends or fails to spend his wages at any particular place

This provision would seem to raise the whole question of how far it is legal for employers to try and place certain places of business (mostly inns and public houses) 'out of bounds' for their employees That such a practice is resorted to in more than one district no one who knows anything of English industrial life will attempt to deny That it is illegal whether from the point of view of the Truck Acts or of the common law of trade interference is less doubtful

Payment in Advance. Whenever, by custom agreement or otherwise, a workman is entitled to receive part of his wages in advance, it is unlawful for the employer to withold such advance, or make any deduction in respect of interest or poundage

It may be worth while turning aside here for an instant to point out that the courts almost invariably require a strict proof of the existence of a custom.

Section 8 of the Truck Act, 1887, enacts that:

No deduction shall be made from a workman's wages for sharpening or repairing tools, except by an agreement which does not form part of the conditions of hiring.

Where articles are made by a person at his own home, or otherwise, without the employment of any person under him except a member of his own family, the shopkeeper or dealer who buys such articles from him must pay him in the current coin and not in kind, under penalty of becoming liable to the fines imposed for infringement of the Act of 1831 (Section 10).

This section only applies to articles under the value of £5, knitted or otherwise, manufactured of wool, worsted, etc.

The factory and mine inspectors enforce the Truck Acts in the factories, mines, and workshops inspected by them.

Fines. Under the Truck Act, 1896, it is enacted that:

An employer shall make no contract with a workman to deduct any sum from his wages by way of fine, unless:

(a) The terms of the contract are contained in a notice kept constantly in a place open to the workman, and in such a position that it may be easily read by him; or the contract is in writing signed by the workman; moreover, the contract must specify the acts or omission in respect of which a fine may be imposed, and the amount of the fine. The act or omission must be one likely to cause damage to the employer or hindrance to his business. The fine itself must be a fair and reasonable one, and

(b) An employer shall not make any such deduction except in accordance with such a contract. No fine can be inflicted unless and until the workman to be fined has been furnished with the particulars for which he is penalised.

Shop assistants come under this Act as well as workmen. Where an employee has been fined illegally under this Act he can recover within six months of the fine.

Employees "Living In." As regards the general provisions of the Truck Act, shop assistants are not equally favoured. There has grown up in the large retail shops of many large towns of England a system known as "living in"—the unmarried assistants are supplied with meals and lodging in lieu of possibly more than half of their wages. The objections to this system are obvious. Men are herded together, the good and the bad without distinction. The State obviously cannot deal with morals, as such; but if the employer were handicapped by statute in his facilities in paying wages in kind, the system would receive a death-blow from which it could never hope to recover.

That is the purpose, without a doubt, of the movement of recent years, which, having resulted in a commission to see how far shop assistants can be brought under the conditions of the Truck Act, will indubitably result in legislation crippling a custom which has become an abuse.

Compensation. The whole question of compensation to workpeople has been settled by the Act of 1906, which, coming into force on July 1st, 1907, may be said to have revolutionised in one important particular the law upon the subject. For the first time domestic servants have been admitted to the advantages of compensation. It would not be possible to give in this place any synopsis of the rules and liabilities under the Act. Suffice to say that the prudent employer will now insure against any liability. We append therefore an ideal form of policy which is accepted by several of the better known insurance offices.

SPECIMEN POLICY

M.......... of .... (hereinafter called "the employer") having paid to the above company the sum of .... on account of premium for the indemnity hereinafter mentioned, it is hereby agreed as follows:

The company indemnifies the employer fully and completely against his or her entire liability (including costs), however protracted, under or by virtue of
The Workmen's Compensation Act, 1906,
The Employers' Liability Act, 1880,
Lord Campbell's Act, 1846,
The Common Law,
The Workmen's Compensation Acts, 1827 and 1900.
In respect of any injury fatal or non-fatal, which, at any time or times during the continuance of this policy, shall happen to any servant while in his or her employ, or while by law so deemed to be.

The company in cases of non-fatal accidents will, in lieu of the payment of half the weekly wages provided by the Workmen's Compensation Act, 1906, allow the employer the full wages paid during the period the employee is totally incapacitated from work up to one month from the date of the accident, and thereafter the benefits allowed by the Act, and will reimburse the employer any reasonable medical expenses he may incur in connection with such accident up to but not exceeding five pounds (£5) in amount.

The company shall at its own cost take upon itself the settlement of any claim, and the employer shall not, except at his own cost, make any payment, settlement, or arrangement. The company shall, at its own cost, take over and conduct and control the defence of any proceedings taken to enforce any claim, and defend the same in the name of the employer.

The employer by the acceptance of this policy agrees:

To give notice to the company at its head or branch office of any accident, within a reasonable period of the time when it comes to his knowledge, and of any claim, either verbal or in writing, made upon him.

To render the company at the cost of the company all reasonable assistance in connection with any accident, or any claim which may arise under this policy, and at the expiration of each year of insurance to furnish a statement showing the total number of persons employed during the year, and to pay to the company any additional premium which may be due in respect of persons employed in addition to those on which premium shall have been previously paid (to which additional servants it is hereby agreed that this policy shall in the meantime apply).

In consideration of an extra premium of .... it is agreed that this policy shall extend to protect the employer against all liabilities under the Workmen's Compensation Act, 1906, to persons not in the employer's permanent service, and temporarily or occasionally employed by him in his capacity of a private householder or of an occupier of office or business premises, or for purposes incidental thereto.

This policy shall be in force for twelve calendar months from the date hereof.

Landlord and Tenant. The folly of the average layman is exemplified in no department of law so much as in the carelessness with which the leasing of houses and rooms is concerned. Tenancies are entered into without agreements stamped and properly sealed, with the result that the tenants entail upon themselves much hardship, and what seems to them to be illegality. At the outset, then, we would offer this golden rule:

Never enter into any tenancy which is for over a year without having a properly stamped and signed agreement. The value of the stamp required will only be a few shillings, and the advantage of security will be incalculable. The tenant should also be careful to note that the lease contains clear and express provision as to the amount of rent, the mode of payment, and the notice required for the termination of the tenancy.

As a matter of practice, most tenants, certainly in humble circumstances and in agricultural districts, are content to take a tenancy without any agreement in writing. In such cases, if they pay weekly, they are weekly tenants; if monthly, they are monthly tenants, and can terminate their tenancy by a month's notice. Causes of perplexity not

infrequently occur where the tenancy has begun on a year's agreement which has come to an end. The tenant continues in occupation. His tenancy is then governed (in point of time) by the mode of payment. If his rent is paid quarterly, he is a quarterly tenant, and must pay and give notice on the day he desires to terminate his tenancy.

Mode of Notice. Notice, whether given by the landlord or tenant, may be verbal, but the onus is upon the person giving it to show that, if verbal, it was properly given. Thus it would not be considered a good notice if the tenant called at the landlord's house and rang the bell, and on being informed that the landlord was not at home, left the verbal notice with the servant to hand on to the landlord. Nor is it a good notice when the date of leaving is placed at a day and time which is not legally in accordance with the requirements of the tenancy. Such a notice is altogether bad, and may be disregarded. The tenancy always expires at midnight on the date fixed for termination of the tenancy, and the tenant cannot be called upon to quit the premises before.

The landlord's remedies against a tenant who fails to pay his rent are dealt with briefly in another place, but here it may be said that where cases arise of tenants "flitting," leaving the house or rooms barred up and empty, the landlord is entitled to break in and obtain possession. If the tenant should happen to have left anything of value behind, the landlord may sell the same to cover the arrears of rent, and such rent as would be due in lieu of proper notice. But he is not entitled to double rent from the departed tenant and a new one, should he have succeeded in obtaining a new one.

Distress. The landlord's remedy where the tenant fails to pay his rent is by "distress," which can only be levied by a certificated bailiff, and must be between the hours of sunrise and sunset. Even then, the landlord must see to it that there is no forcing or breaking into the house, for the rule of the law is that "an Englishman's house is his castle." The bedding of the tenant and his family, and wearing apparel in actual use, and tools and implements of his trade to the value of £5, must not be distrained upon. Goods belonging to a lodger or visitor in the house should not be seized, but it is incumbent upon them to serve a declaration of ownership upon the landlord, accompanied by an inventory specifying the property in question. It may also be added that:

Kitchen ranges, stoves, coppers, grates, and other fixtures of the like nature put up by the tenant for the more convenient or profitable use of the demised premises, and which he is entitled to sever and remove during the term, are not distrainable for rent.

The other rules for distress, inasmuch as the process is compulsorily in the hands of experienced people, need not be given here. It will be enough to add for the benefit of unfortunate tenants that the penalties for illegal distress are very heavy.

Another branch of house letting of importance to tenants concerns the question of repairs.

Repairs. Probably it would always be safer to specify more fully than is habitual at present the repairs for which the landlord is responsible, and those which should be upon the tenant. At present, the favourite phrase is "*tenantable repair*," and the necessity of keeping the house in this condition is upon the landlord. But the meaning of that phrase is rather an elastic one. It is not, indeed, possible to define it more than generally. In as few words as possible, it may be said that the landlord must keep the house in a habitable condition. If the roof falls in, or one of the ceilings, if the cellar becomes full of water, he must see to rectifying these defects. But he will not be responsible for broken sash cords, or door handles that tumble off, or if the chimney smokes.

Failing, however, any express agreement, the landlord has no such liability at all. There is no implied warranty on his part that he will keep the premises habitable, or rebuild them in case the roof falls in or they are burnt down. So a tenant who is burnt out will find himself under the unpleasing necessity of still having to pay rent. And more than that, the landlord can get the insurance money for the destroyed premises and yet refuse to rebuild them. Surely this may be said to be a branch of our law conspicuous by its oddity.

Fair Wear and Tear. The responsibility upon the tenant, in the absence of any express agreement, is to leave the premises at the expiration of his tenancy in a reasonably clean condition, fair wear and tear being allowed. But if he has pulled down a wall during his tenancy he must rebuild it, of course, unless he has obtained the landlord's permission for the structural alteration. This branch of our subject includes the question of fixtures, the legal aspect of which has given rise to much perplexity in the past.

The broad rule is that the tenant, at the expiration of his lease, may *remove trade and ornamental fixtures, but he must take care that in so doing he does no damage to the fabric.* Thus, a chandelier put up by the tenant may be taken down only if the ceiling is left in proper condition. Trees and shrubs planted by the tenant could be removed if by so doing no harm was done to the garden—a rather prohibitive condition. The tenant in such cases would be in a better condition if he happened to be a nurseryman, and could describe these articles as trade fixtures.

A shop window or counter or show-cases can be removed at the end of the tenancy, but the premises must be restored to their former condition. It will be seen then that the subject is one on which no definite rules can be enunciated. The safest course in all cases is to make these alterations the subject of express agreement with the landlord. The tenant who, for instance, is at the expense to fit up the premises as a shop, and then discover that it will cost more to remove his fixtures, must bear in mind that he will not be entitled to any compensation from the landlord for the things left behind—unless, of course, the whole matter had been the subject originally of express agreement.

PERSONAL LAW

"He who is his own lawyer has a fool for his client" is a saying which has in it much truth and much fallacy. At any rate it applies to lawyers as well as laymen, for the family which had good cause to rue home-made law was that of a former Lord Chancellor who drew up his own will with remunerative consequences to the class from which he sprang. But the drafting of legal documents is another story. And here it may be said at the outset that the drafting of legal documents, wills, contracts, bills of sale, deeds of gift, should never be undertaken by amateurs, however vital the needs of economy. If a man has twenty pounds to leave behind him, it will be far cheaper in the long run to have that trumpery amount conveyed by a proper will executed by a qualified solicitor. Home-made drafts are short cuts to litigation; the man who uses them may write himself down penny wise and pound foolish.

But in daily life legal points arise, too trivial to take to a solicitor, or perhaps too sudden to leave time for consultation. Often in a man's business or employment, or in his relations with his landlord or his tenants, or with the doctor who attends his children, or the schoolmaster who teaches them, he takes a false step sufficient to put him out of court for ever so far as that particular case is concerned. Husband and wife, through ignorance of a minimum of law, may entail consequences upon themselves of a most uncomfortable kind, to say nothing of the legacy of woe daily left to children by married persons who are ignorant or careless, or both.

Husband and Wife. The only bars to marriage under our law are disabilities through five causes:

(*a*) Mental Incapacity. A marriage with a lunatic "so found by inquisition" is void, or with a person who, though not the subject of an inquisition, can be proved to have been insane at the time of the marriage. "Insanity" must, of course, be taken to mean real, definite insanity, not mere oddness or eccentricity. It may be added that to go through a form of marriage with a declared lunatic (so found by inquisition) is punishable as a very serious contempt of court.

(*b*) Age. Marriages contracted under fourteen by the male and under twelve by the female are voidable—that is, they can be annulled at the will of either of the parties on reaching the marriage age.

(*c*) Relationship. The prohibited degrees of relationship are to be found in the Prayer Book. These include illegitimate relations and relations by the half-blood. Thus, a man may not marry his deceased wife's step-sister, though there may have been no blood tie between the women at all; also a man may not marry his deceased wife's illegitimate daughter.

(*d*) Prior Marriage. The existence of a prior marriage renders a new marriage absolutely null and void.

(*e*) Physical Incapacity is a ground for voiding a marriage. The distinction between *void* and *voidable* in the above paragraphs must be clearly understood. *Void* means null from the very beginning—never anything else: while *voidable* signifies that the marriage is a good one until either of the parties chooses to void it. But in the latter case, if it could be proved that a party chose to take advantage of its voidable character through capriciousness—*i.e.*, long after he or she knew that it was possible, the court might very well refuse to allow it to be voided.

Formalities of Marriage. Marriage can be solemnised according to the rites of the Church of England, or civilly. Thirdly, there are Nonconformist marriages.

Church of England Marriages are either by Banns, Licence, "Special" Licence, or Registrar's Certificate.

(1) Banns. The Marriage Act, 1823, directs that:

All banns of matrimony shall be published in an audible manner in the parish church or in some public chapel, in which chapel banns of matrimony may now or may hereafter be lawfully published, of or belonging to such parish or chapelry wherein the parties may be married shall dwell, according to the form of words prescribed by the rubric prefixed to the office of matrimony in the Book of Common Prayer, upon three Sundays preceding the solemnisation of the marriage, during the time of Morning Service or of Evening Service [*if there shall be no Morning Service in such church or chapel, upon the Sunday upon which such banns shall be so published*], *immediately after the Morning Lesson, or whensoever it shall happen that the parties to be married shall dwell in diverse parishes or chapelries, the banns shall in like manner be published in the church or in any such chapel as aforesaid belonging to such parish or chapelry wherein such parties shall dwell.*

If the names of the parties are misstated in the publication of the banns, and this misstatement is the result of false information given *with the knowledge of both parties*, the marriage is void. One wrong name might not render the marriage void, though this is possible. If the misdescription can be proved to have been due to no fraudulent intention, or if only known to one of the parties, the marriage is good. A misdescription of status, as where a widow describes herself as a spinster, does not matter, and has no effect upon the validity of the marriage.

Seven days' notice of the publication of the banns must be given to the clergyman of the parish: consequently it must follow that *twenty-two days'* residence is compulsory in the parish on the part of the party who has to obtain residence in the parish for the publication of banns. This, of course, refers to a person who has no parish of his or her own. Then, "a traveller is a parishioner of every parish he comes to": accordingly the man (without a parish of his own) who desires to marry a woman, say in Folkestone, must himself become a resident in that parish (or any parish where he chooses that his banns shall be published) by remaining there seven days to cover the notice to the clergyman, and fifteen days to cover the three Sundays when the banns are put up. If the marriage does not take place within three months after the complete publication, then there must be republication for three Sundays.

The marriage must be solemnised in one of the parish churches in which the banns were published.

(2) Licence. Where it is desired to dispense with banns, Church of England marriages can be by licence, to be obtained from the episcopal head of the diocese in which the marriage is to take place. No licence can be granted unless there has been a residence *for fifteen days by one of the parties* in the parish where the marriage is to be celebrated. Then before the licence is granted one of the parties must swear before the bishop's officer that there is no lawful impediment of kindred and that there has been fifteen days' residence, and if either party is a minor, and not previously married, then that the consent of the parent or guardian has been obtained. A false oath in regard to any of these particulars is a misdemeanour and punishable as such.

The licence must be produced for the clergyman at the marriage, and will be retained by him. The cost of such a licence varies in different dioceses from £2 to £4.

(3) Special Licence. Special licences, which cost £30, can authorise marriage without residence, at any hour of the day or night, and in any place whether consecrated or not. The special licence is granted only by the Archbishop of Canterbury, for any part of England, and the application for it must be accompanied with an affidavit giving particulars as to names, etc., and made to the office of the Vicar-General.

(4) Registrar's Certificate. Marriages may also be solemnised in church on a registrar's

certificate. This certificate is also used in Nonconformist marriages and will be treated under that head.

Nonconformist Marriages. By the present laws of the land marriages between persons belonging to denominations other than the Church of England are validly solemnised in the places of worship of the denominations to which the parties belong. A notice to the registrar is required, after which a certificate or licence is granted and the marriage can proceed.

A registrar's certificate or licence is valid for marriages in Church of England or Nonconformist places of worship, or for civil marriages.

A form must be procured by one of the parties from the registrar's office, and filled in with the full names, status, etc., of the contracting parties. Anyone who wilfully signs a false statement knowing it to be false is guilty of perjury and can, on conviction, be sent to penal servitude. At the time of giving notice the party must also make a solemn declaration of seven days' residence (fifteen, if the marriage is to be by licence) in the district of the superintendent registrar.

If either of the parties is a minor, then this solemn declaration must contain a statement that the marriage is taking place with the consent of those entitled to withhold it.

A false statement wilfully made is perjury, and can be punished, on conviction, by penal servitude. But such false statement does not render the marriage void.

The notice of such a marriage must be conspicuously exhibited in the office of the superintendent registrar for twenty-four hours prior to the solemnisation of the marriage, to give an opportunity for any authorised objection.

Following upon the notice, the parties can take their choice of a licence or a certificate. The former is the more expensive and the more expeditious. In the case of the licence also the need of a public exhibition of the notice is dispensed with. The fees in either case are not very high, and the exact formalities as to prior residence in the district will always be given at the office of the superintendent registrar.

The certificates or licences above referred to are valid for the solemnisation of marriage in a place of worship or in a registrar's office.

Marriages must in that case be solemnised in the usual form before the superintendent registrar in the presence of two witnesses.

Marriages Abroad. The question of marriages abroad opens too wide a subject to be dealt with in an article written for laymen. One golden rule taken to heart by British men and women in foreign countries will save much future unhappiness. Never enter into a marriage contract with a non-British subject without first finding out from the British Consul in that particular place how to set about making the ceremony a valid one, both by English law *and the law of the land in which the marriage is celebrated.*

The rule of our law is that every child born of the wife after lawful wedlock is presumed begotten of lawful intercourse, and therefore legitimate.

But if it can be conclusively proved that the husband has had no access to his wife the child can be bastardised.

The old days, when a husband could chastise his wife or take her to Smithfield, there to sell her to the highest bidder, have passed away for ever. In the eyes of the law, as it stands to-day, a husband is entitled to be master in his own home, but is no longer allowed to be tyrant. A married woman has many legal opportunities of getting away from a husband who is capriciously domineering, orders for the sake of ordering, or attempts to rule the household to beyond the limit of what is really reasonable.

Married Woman's Property Act. It is obviously impossible in this place to give the thousand-and-one details of the law governing the relations between husband and wife. Inasmuch as the bedrock of those relations is usually the question of property, it will be enough here to refer fully to what may be called the Magna Charta of married life—the Married Woman's Property Act of 1882. The main clause of the Act is the first. For that reason it is given in full in this place.

1.—1. *A married woman shall, in accordance with the provisions of this Act, be capable of acquiring, holding, and disposing by will or otherwise of any real or personal property as her separate property, in the same manner as if she were a femme sole, without the intervention of any trustee.*

2. *A married woman shall be capable of entering into and rendering herself liable in respect of and to the extent of her separate property on any contract, and of suing and being sued, either in contract or in tort, or otherwise, in all respects as if she were a femme sole, and her husband need not be joined with her as plaintiff or defendant, or be made a party to any action or other legal proceeding brought by or taken against her; and any damages or costs recovered by her in any such action or proceeding shall be her separate property; and any damages or costs recovered against her in any such action or proceeding shall be payable out of her separate property, and not otherwise.*

3. *Every contract entered into by a married woman shall be deemed to be a contract entered into by her with respect to and to bind her separate property, unless the contrary be shown.*

4. *Every contract entered into by a married woman with respect to and to bind her separate property shall bind not only the separate property which she is possessed of or entitled to at the date of the contract, but also all separate property which she may thereafter acquire.*

5. *Every married woman carrying on a trade separately from her husband shall, in respect of her separate property, be subject to the bankruptcy laws in the same way as if she were a femme sole.*

The remainder of the Act is equally important. It provides remedies of married women for protection and security of separate property. Another section refers to the wife's ante-nuptial debts, for which the husband is responsible only to the extent of any property of hers of which he has the enjoyment. But whereas that Act has the effect of putting married women on an equality with all other adults in respect to the owning of property, the law has gone a step further and endowed them with a privilege denied to everyone else. This is the *Restraint of Anticipation*, which is permitted to be added to any gift of land or income made to a married woman. During her husband's lifetime she may enjoy this income or the land as her separate estate, but she may not alienate it. Directly he dies she may dispose of it as she pleases—capitalise it, if it is income; sell it, if it is land; give it away or exchange it.

These broad lines, then, are sufficient to show the main features of the law governing marital relations where property is concerned. One important subsidiary question remains: *How far is a husband*

responsible for his wife's debts? It can only be said that the law is by no means settled. For her debts contracted prior to the marriage he is responsible only to the extent of her estate which he may enjoy.

But the debts contracted during marriage are another matter. He may safeguard himself, it is true, by advertising in the newspapers that he will not be responsible, but that is a counsel of despair not likely to be thought of until the mischief is done. At the same time there is the point of view of the creditor to be considered, the tradesman who sells the goods and has a right to expect payment.

Probably in no recent instance has the need of a code ever been more emphatically instanced. Paquin *v.* Beauclerk (otherwise Holden), the last recorded case upon the subject (1906), equally divided the House of Lords, with the result that the Lord Chancellor (Loreburn) and Lord Macnaghten took one view, while their two legal brethren, Lords Robertson and Atkinson, took the other.

The result is to make it possible only to state the rough rule with considerable doubt. Within the next few years, months even, what lawyers now regard as settled upon the subject may be altered, and a definite code be established as to how far married women may contract debts on their own and their husband's credit.

The Tradesman's Liability. As the law stands, then, a tradesman who supplies a married woman with necessaries befitting her apparent station in life, or with goods for use in the household, must look for payment to the husband. Groceries supplied to a villa residence in Sydenham must be paid for by the husband. It matters not that he has given his wife fifteen pounds a week for household expenses, and she has spent the money instead on cards and racing and finery; the unpaid household bills are accumulating against his credit, and he must pay them or no one else can be made to. But the tradesman is called upon to exercise a little discretion. The wine merchant who, on the wife's order, sends in five dozen of his best brand of champagne to the house in Park Lane where he knows the husband to be living is in a worse position as regards the wife's liability than if he takes an identical order for a lady whom he has every reason to believe is a widow, though living in an equally expensive neighbourhood. Again, the draper who sells a bricklayer's wife an expensive piece of silk may find it difficult to prove the liability of the bricklayer to defray the bill. But these are refinements which lead only to confusion. Summed up in a simple sentence, the present rule is *Caveat vendor*, the creditor supplies a married woman at his own risk.

The End of Marriage. The methods of ending marriage other than death are numerous. If the wife is guilty of misconduct the husband can obtain a divorce. If she deserts him, he can no longer compel her to return to him, except through the process of the court, and to the extent that that will help him. Certainly he may not employ physical violence, or constraint in any shape or form. Just as the Married Woman's Property Act is the charter of her liberties as regards property, so the *Jackson Case* may be called the seal of her freedom. The decision in that case laid it down once and for all, so far as our law is concerned, that the wife could not be constrained to live with her husband against her will. Both parties are now in the same position.

The party desirous of cohabitation, whether husband or wife, may sue for restitution of conjugal rights. The other side failing to comply within a specified period, the only course then left is to petition for a judicial separation. This does not allow either side to marry again, but neither side can afford to disregard it without the consent of the other. It acts as an absolute bar to any meeting. The party against whom it is granted, if the husband, or the wife with money, will also find him or herself burdened with the payment of maintenance to the other side, while the custody of the children will also be in the hands of the petitioner, though the respondent will not be denied reasonable access to them.

The Wife's Claims to Divorce. The same remedy is in the hands of the wife whose husband has been guilty of misconduct; for a wife cannot obtain a divorce unless she can prove that her husband, in addition to misconduct, has also been guilty of legal cruelty. Mere rudeness or an occasional outburst of temper on the husband's part is not enough. The wife must prove that her husband has been systematically cruel, and that his behaviour has had a bad effect upon her health. She may also obtain a divorce if the misconduct is coupled with desertion without any reasonable cause for a minimum period of two years. There are certain crimes on the part of the husband which entitle the wife to petition for divorce. It remains to state that the husband against whom a decree is made will have to provide for the maintenance of his divorced wife and children, and though the custody of the children will be with the wife, he will not be denied reasonable access to them. It is different with the wrongdoing wife. The court will not grant her access to her children under 16 years of age. With children over 16 years the court has no concern, and refuses to make any order. It must be noted that where a divorce is granted, a *decree nisi* is granted in the first instance, and the parties are not free to marry again until this decree has been made *absolute*. No decree will be granted where it can be proved that the petitioner subsequently condoned the misconduct, as knowingly resuming cohabitation with the guilty party. Nor will a decree be granted to a petitioner who has been proved to have been privy to the act of misconduct, nor to the party whose own conduct has palpably and glaringly conduced to the misconduct. Disappearance of a party to the marriage is not in itself a dissolution of the marriage. The other side must get leave from the matrimonial court to presume the death of the disappeared: and whether this will be granted will depend on the length of the disappearance and the likelihood of death. To marry without such permission is bigamy.

One word of general interest to laymen must be mentioned. Poor people are now enabled by law to petition for a divorce at a very small cost. The Probate and Divorce Division of the High Court, Law Courts, Strand, London, should be applied to in the first instance, and the mode of procedure will be pointed out.

Parent and Child. The modern parent is no longer an absolute tyrant. He is a constitutional monarch. He has a right to exact obedience from his child who is still a minor (under 21 years); he can withhold his consent to his child's marriage, and no marriage can be solemnised without that consent. But it is a very negative sort of privilege. Thus the solemnising clergyman, or the registrar who issues the licence or the certificate, may assume that the consent is given, unless he is informed that the contrary is the case. Consequently the onus is upon the non-consenting parent, and when it is remembered what opportunities for secret marriages our very elaborate civilisation offers young persons, it will be seen that in modern life the parent has very little say in the matter. The fact that he opposes

the marriage when he learns about it does not render the union null and void. Of course, a parent can use reasonable constraint on the person of the child—a young person predisposed to a specific act of matrimony against the wishes of the parent may be even locked up in a room, but such " durance vile " must not go beyond what is reasonable discipline. It must not savour of cruelty at all, nor have any injurious effect upon the health of the child, for here the community steps in, and it becomes a matter for the police court.

The parent, again, is the chief arbiter as to the religion of the child, or he may decide to teach the child no religion at all. Again, he may decide what secular instruction the child is to receive and where, but he must arrange that the child *is* taught, or the State will step in and do it for him. The parent, however poor, will be responsible for the maintenance of the child, and if the latter is starved or neglected wilfully (save, of course, through the misfortune of the parent), the latter is criminally responsible. Conversely, adult children are civilly responsible for the maintenance (or a contribution thereto) of destitute parents. Parental control does not continue in the case of children over 21 years.

Wills. No such view of law as the present one would be quite complete without a few words on the subject of wills. Persons who have property to leave should be warned to avoid home-made wills. In no other branch of law is the rule so often exemplified that " the man who acts as his own lawyer has a fool for a client." But if testators will insist upon making their own wills, let them make a point of simplicity, unambiguity, and clearness. The use of technical words is to be deprecated. If they employ them, it will be assumed that they know the meaning of the words they use. Neither stamps nor seal are now required to the validity of a will. It may be drawn up in any form the testator pleases, but it must be signed at the end by the testator and two witnesses in each other's presence. Creditors and executors are competent witnesses, but not beneficiaries. It may be added, however, in this respect, that the will is bad only so far as it concerns the beneficiary witness. But such a beneficiary witness may be given a legacy by a codicil which is duly witnessed by other witnesses.

Intestacy. Intestacy is the term applied to a person who dies without leaving a will. The rules for the division of such property are very clearly defined. But no family of an intestate should attempt to divide the estate except with the help of a solicitor.

The office of executor is not by any means an easy one. It is his duty to wind up the estate, and he must bear in mind that his responsibility for proper administration is a very heavy one. It is open to him to renounce the position at the outset, but if he accepts it is incumbent upon him to carry the will through to probate. If this is not done within six months he lays himself open to a very heavy fine. The Chancery Court however, will give relief in special cases. A public trustee has now been appointed by Act of Parliament, and come into existence from January 1st, 1908. He is a government official who, in return for a small fee, acts as trustee, and (if required) executor, in small and large estates. The security thus given against the fraudulent conversion of trust funds is obvious.

A SHORT DICTIONARY OF TERMS USED IN LAW

AGENT—A person authorised to contract legal obligations and acquire legal rights, and generally to enter into relations involving rights and duties on behalf of another, from whom his authority is derived.

Agreement—A mutual contract or consideration between the parties.

Aliens—Subjects of a State other than that in which they happen to be residing temporarily or permanently.

Ancient Lights—Uninterrupted enjoyment of light for twenty years.

Antenuptial Settlements—Settlement of property, etc., upon an individual prior to his (or her) marriage.

Appearance—Attendance, either in person or by proxy, at a court of law in reply to a demand for reparation.

Arson—Deliberately setting fire to buildings or such property as mines, crops, etc.

Assignment—The conveyance by the holder of a lease or part of a lease to a third person or set of persons.

Assurance—Guarantees to cover risks and compensate for losses, given by one party to another for payment.

Attestation—The act of witnessing: the signatures of the witnesses when complete.

Attorney, Power of—The delegation capacity to enter into binding arrangements on behalf of the person so delegating.

BAIL—Security taken by the court that a person charged will attend at a future date to answer to the charge.

Bailee—The holder of goods to obey the direction with which the delivery to him is made.

Bailiffs—Officers of the court employed to prosecute directions and orders of the court as to ejectment and distress for rent.

Bankruptcy—Insufficient assets to cover all just claims, and such insufficiency publicly declared by some act.

Barratry—Wilful damage to ship or cargo done by master or any member of the crew, without the privity of the owner.

Barring of Action—Limiting of right to bring an action after a certain interval of time.

Battery—A hostile touch or the hostilely throwing of anything at another person, or spitting at him. Practically a convertible term in law for Assault.

Bequest—Property left by will.

Bigamy—The offence of going through the ceremony of marriage when the first husband or wife is still alive, and the former marriage has not been dissolved.

Bills of Exchange—A bill of exchange is an unconditional order in writing, addressed by one person to another, signed by the person giving it, requiring the person to whom it is addressed to pay on demand, or at a fixed and determined future time, a certain sum in money, to, or to the order of, a specified person, or to bearer.

Bills of Sale—Documents operating as the transfer of property from vendor to purchaser, or as the evidence of such transfer.

Breach of Condition, Contract, etc.—Breaking the agreement to perform a certain act, etc.

Burgess—Enrolled and fully qualified member of a borough.

CESTUI QUE TRUST—The person for whose benefit the trust has been instituted.

Champerty—Bargain between third party and a party to a suit, to divide the object of the suit (land), if successful; supplying in return money to prosecute the suit.

Chattels—Personal property.

Cheque—An authorisation to the bank (or holder of any deposits) to pay a sum of money belonging to the drawer of the cheque to the payee.

Claim, Statement of—The legal document used in proceedings to set forth the demands of the suitor who is the plaintiff in the case.

Collusion—A private understanding between parties, made to influence or negative the course of justice. Used principally in cases in the Divorce Court, where husband and wife have a private understanding with a view to obtaining a dissolution of their marriage.

Compounding—Agreeing to suppress a crime, so that the wrongdoer may not be brought to justice.

Conjugal Rights—The rights of husband and wife to the society and support of the other. The compulsory common life.

Consideration—The reason demanded in law for the passing of any property from one person to another.

Contracts—Agreements between two or more parties to perform some act or pass property, etc., etc.

Contributory Negligence—Negligence in law on the part of any victim of an accident, disqualifying him from obtaining compensation from the employer or person responsible primarily for the accident.

Copyhold Estates—Tenancies held from the lord of the manor and entered in the Court Rolls of the Manor.

Copyright—The property in writings or paintings, etc., which prohibits their reproduction save at the will of the owner of the (copyright) property.

Corporations—Bodies of individuals or shifting aggregates or institutions treated as single individuals as respects their powers to sue or be sued, but differing from individuals in this that they are immortal.

Counterfeiting—Making base imitations of the coin of the realm.

Counterpart—The duplicate of a document—*e.g.*, the lease, deposited with the lessor.

Covenants—Clauses in a lease promising to do or abstain from doing certain acts and duties in connection with the tenancy.

Curtilage—The same common fence surrounding a house and outbuilding.

DAMAGE FEASANT—Any person whose property is injured by the cattle of another straying thereon, without any contributory fault of his own, is entitled to seize the cattle and retain them until he has been compensated for the damage done. This is known as "distress damage feasant."

Damnum Sine Injuriâ — Damage caused without a wrongful act.

Debt Judgment—Debt found owing by the decision of the court. Money owed as the result of a judgment of the court.

Dedication of Highways—Devoting a thoroughfare (through specified legal means) to the use of the public.

Defamation—Blackening the character of another person, either by words uttered or written.

Default—Failure to appear in satisfaction of legal proceedings.

Delivery—The legal passing of the property in goods.

Demise—The granting of a term of years' interest in property.

Devise—Testamentary grant of property.

Dissolution—Legal termination of a contract—usually employed with regard to the contract of *partnership* or *marriage*.

Distress—"The taking, without legal process, cattle or goods as a pledge to compel the satisfaction of a demand, the performance of a duty, or the redress of an injury." (Woodfall.)

Domicile—The place where a person has his permanent abode, and whither (when absent) he has an intention of returning.

Drawee of Bill—The person in whose favour a bill is drawn (drawee or payee).

EASEMENT—A right over another's land, under which some service or enjoyment is vested in a person who has no property in the land, and no right to draw any profit from it.

Ejectment—Forcible expulsion of defaulting tenants from house or land.

Embezzlement—Robbery by a clerk or servant of his employer's money, etc.

Employers' Liability—Responsibility of employers to compensate workpeople injured in their service, by any cause other than the workman's own fault, or the fault of a fellow-work man.

Entail—The line of succession to land indicated.

Estate Duty—The taxes required to be paid on succession.

Execution of Judgment—Enforcement of decree of any court.

Executors and Administrators—Officers appointed under a will to fulfil the terms of the will and administer (so far as required) the estate.

FACTORS—Agents employed and empowered to buy and sell.

Fee Simple — Practically absolute ownership of personal property.

Fee Tail—A limited estate, or property in an estate.

Felony—"An offence which occasions a total forfeiture of either lands or goods or both, at common law, and to which capital or other punishment may be superadded according to the degree of guilt." (Russell.)

Foreclosure of Mortgage—Taking complete and actual possession of property upon which money has been raised, in default of repayment of said sums.

Forgery—Personating another through the means of counterfeited writing.

Fraud—Wilful misrepresentation in entering upon an agreement.

Freehold—Estates held in fee simple, fee tail, or for life. [q. v.]

GRACE, DAYS OF — Extensions allowed by law before a just debt, etc., becomes due after the actual date of repayment has vested.

Guarantee—The acceptance of the obligation of a third party to complete some agreement.

HEARSAY EVIDENCE—Report of words used by a third party not present before the inquiry.

Hereditaments—Inheritances applied to land.

Heriot—Feudal "service" due to the lord of the manor on the death of the tenant.

Highways—A way open and common to all the King's subjects.

Hire-purchase—Payment for goods, the actual possession of which has passed already to the purchaser, by instalments.

IMMEMORIAL USAGE — Custom which has obtained so long as the memory of man can extend back.

Indorsement—Signature of payee (or drawee) acting as negotiation of the bill.

Infants—Legal description of those who cannot enter into contracts for reasons of age.

In Formâ Pauperis—Facilities for suing or defending in courts of law where the suitor is too poor to employ legal aid.

Inhabited House Duty—A tax upon occupied houses, the incidence of which falls upon the occupier or landlord according to the rent paid.

Inland Bill of Exchange—A bill both drawn and payable upon presentation within the British Isles.

International Copyright—Protection of literary property extending over its production in foreign countries.

Interpleader—Process to ascertain real ownership of goods seized under a distress for rent.

Intestacy—Disposal of the property of a deceased person who leaves no will.

JETTISON—Throwing cargo overboard to save the ship.

Joint Tenancy—Two or more persons holding land in common.

Judicial Separation—Legal status (short of the dissolution of the marriage tie), pronounced by the Divorce Court, entailing living apart, but not entitling the parties to re-marry.

LADING, BILL OF—Document containing description, etc., of cargo consigned to a ship.

Larceny—Feloniously taking another person's property against his consent, with a view to converting to use of the taker.

Lien—Hold on property vested in persons having some claim upon the actual owner.

MALICE—The conscious violation of the law to another's detriment.

Market Overt—"A fair or market held at stated intervals, in a particular place, by virtue of a charter or prescription. In the City of London every shop is, on every day except Sunday, a market overt for the sale of goods usually sold therein." (Chitty.)

Memorandum of Association—Document demanded by law and containing the terms governing the formation of a limited liability company.

Misdemeanour—Any crime less than a felony (q.v.).

Mortgage—Security given by a debtor to his creditor, either on land or personalty, to safeguard the repayment of the amount owed.

Mortmain—Transfer of property to any corporation as distinct from individuals or cluster of individuals.

NECESSARIES—Articles supplied to infants or married women which they are bound to pay for personally as essentials to their mode or condition of life.

Negligence—Acts of commission or omission other than those likely to be done by a reasonable man.

PAROL—Verbal as opposed to written.

Perjury—Swearing to what one knows is false.

Personalty—Property in cash and movables as opposed to realty (land).

Privileged Communications—Letters to solicitors from their clients; or from a person to any professional man who he is consulting, and concerning matters which it is the professional man's calling to deal with.

Procuration, Powers of—Delegating authority to bind another to agreements, etc.

Promissory Note—A promise in writing to pay certain sums, made without qualification or condition.

RATIFICATION—Confirmation of any agreement.

Receiving Order—Term used in bankruptcy for appropriating the assets of a bankrupt towards the payment of his creditors.

Representations Fraudulent—Statements of untrue character made with the object of inducing others to enter into some agreement which they would not make if they knew the facts.

Repudiation — Refusal to complete terms of a contract, on the ground that said contract had been obtained by the other party by misrepresentation, etc.

Reversion—Possession of realty or personalty vesting after the death of the actual possessor.

Rights of Way—Public capacity to cross private property at certain points [see *easement*].

SEISIN—To become possessed of realty.

Stoppage in Transition—The stopping of goods on their way to the perspective possessor; for debt, and so on.

Surety—Individual who accepts responsibility for the performance of some obligation on the part of another.

TORTS—Civil wrong for which one is liable civilly, but not criminally.

Treasure Trove—Valuables, to which no owner can be traced, found either in public or private land.

WRIT—Legal document used in process of civil and criminal actions, setting forth the cause of action and formally demanding the satisfaction claimed by the plaintiff.

LAW *concluded*

WOOD-TURNING

Woodworkers' Lathe and other Tools. Work Between Centres. Chuck Work. Measurement. Square Turning. Ornamental Objects

Continued from page 6756

By JOSEPH G. HORNER

The Lathe. The craft of wood-turning is very ancient. It was formerly done by a reciprocating mandrel, operated by a bow and cord; or by an overhead spring pole, operated by a treadle. The bow and cord still survive in the East. All modern wood-turning lathes are fitted with continuously running mandrels. Lathes for wood-work are much plainer than those for metal turning, seldom comprising more than a plain ungeared headstock, a simple poppet, and a hand tee-rest. For some engineers' pattern turning, a plain slide rest is fitted and a large face-plate, or a special face lathe. But with these exceptions, and that of the ornamental turner, wood-turners' lathes have no aids to supplement the work of the hands. The fact is, a skilful turner is more nearly independent of his lathe and tools than most craftsmen, and excellent work is done by such men on lathes that would excite the derision of the engineer or the wealthy amateur. Wood-turning is one of the crafts in which manipulation is the supreme factor, one in which the essential tools are few in number, and very simple in character.

A large, high-class lathe, much superior to those usually found in wood-turners' shops, is shown in **1**, made by T. White & Sons, of Paisley. It is all of iron, while wood figures largely in much lathe construction. It is of large size, 12-in. centre, designed for pattern turning, and general utility. The following are the principal parts: the *bed*, A, having at one end the *headstock*, B, with the four-stepped cones, C, turned inside and out for perfect balance, and driven from the cones, D, on the countershaft, fitted with fast and loose pulleys. E is an iron *face-plate*, to which work can be screwed directly, or through an intermediary plate of wood. F is the *fork*, or *prong* centre. G is the *loose poppet*, or back poppet, or movable poppet, or loose head, and its centre is the *back* centre. It is fitted for turning long tapers, as on columns, by utilising the cross-traverse movement provided. The tool rest commonly used is the *tee-rest*, H, with which nine-tenths of wood-work is done. But for long pieces, a *slide-rest*, J, is provided, comprising the tool holder on a cross slide, adjustable across the top of the saddle, which is fitted to the bed with vee'd edges, and an adjustable strip. The saddle is travelled up and down the bed by a rack, K, the pinion of which, L, is actuated through a pair of gears, N and O, by the lower lever handle, M, the upper handle being for the cross traverse. A nest of drawers, P, is formed underneath the bed to receive the tools, and a rack, Q, adjacent, receives face-plates. R is the *back board* for tools in use.

Wood-turning Tools. The principal operations are performed with two tools only, the *gouge* [**2**] and the *chisel* [**3**], each being used in three or four different sizes. Both are true cutting tools, both require practice and skill in their manipulation, but all conceivable shapes are outlined by deft handling of these two. True, there are many others which complete a turner's kit, but they are only used for occasional finishing, smoothing, and correcting. All the roughing out, and by far the greater portion of the finishing also, are done by these two very simple tools. We will consider them and their work in turn.

The Gouge. This [**2**] is like no other gouge. It has a considerable convexity of the cutting edge, the reason of which is to prevent, or to lessen risk of hitching or catching of the revolving work against one corner of the tool, which would happen if an ordinary firmer gouge were used for turning; or if the gouge were ground like **4**, instead of like **5**. It is this rapid revolution of the work, with the centrifugal action, tending to knock the gouge away, that the turner, consciously, or instinctively, born of habit, always has to bear in mind. The beginner, after sundry hitchings, and damage to the work, his hands, or the tool, or all in unison, soon learns to present the gouge warily. The thing to remember is not to allow the work to catch in the sides of the gouge, but to do the cutting at and near the point *a* only. Bearing this in mind, faces that are perpendicular to the axis of rotation can be roughed down safely, the back of the gouge being held next the face being cut. Concave and convex portions are also easily cut, the back of the gouge always lying next the face being turned.

When turning a parallel, or straight portion, the gouge can be held straight forward [**6**]; but, generally, more rapid reduction can be effected by turning with a diagonal cut, or sideways, changing the direction of cutting towards right and left alternately. Deeper cutting can be done by this device than by straight-forward presentation, though the latter is suitable for taking finishing cuts. To suit details of work of different dimensions, gouges are made in different sizes, from $\frac{1}{4}$ in. to $1\frac{1}{4}$ in., so that either fine details or heavy roughing down can be done by selecting suitable gouges. The *handles* of these gouges [**2** and **6**] will be noted as being characterised by much leverage. To this, in fact, they owe so much of their value. The workman is thus able to control their movements in opposition to the severe stresses caused by the revolution of the work. A firm grip is taken at the fulcrum—that is, the place where the gouge lies on the rest [**6**]. The gouge is gripped there between the forefinger and thumb of the left hand, while the end of the handle, gripped in the right hand, is kept in constant movement in arcs of circles to suit the nature of the cutting being done. In some cases the side of the gouge is presented, as in taking a finishing cut in a bore [**7**]; **8** is a gouge used on the slide rest.

The Chisel. This [**3**] is the only turning chisel with a doubly bevelled edge like that of the axe, though used in quite a different manner. It is presented and traversed against the revolving work, cutting shavings at and near the obtuse-angled end. The degree of pressure exercised is controlled by the hands of the workman. The tool is gripped on the rest [**10**] by the forefinger and thumb of the left hand, similarly to the gouge, while the right manipulates the handle. Like the gouge, the chisel will turn straight and convex

portions, though not concave ones, unless of large radius. The point to observe is that cutting must not be done far away from the point, *a* [9], and, say, over one-third of the width from the point, otherwise the tool is liable to be caught, and damage the work. It can be used indifferently in right and left directions [11]. The chisel, like the gouge, if used properly, leaves a very smooth surface. The acute-angled corner of the chisel fulfils the special function of cutting down perpendicular, or nearly perpendicular faces [12], and of severance. Being so keen a wedge, it will cut deeply and rapidly, leaving the smoothest possible face. It cannot be used for turning like the other angled corner, but would be caught by the work if presented thus.

Scraping Tools. Though the gouge and chisel are the sheet anchors of the turner, it is obvious that they cannot cover all details of work, and especially in pieces of large dimensions. Thus, a disc on the face plate cannot be turned and finished with the side chisel. For this a *firmer* chisel, acting as a scrape, must be used. A deep hole can be roughed with the gouge, and partly smoothed with the keen angle of the side chisel, but a true, smooth face must be finished with a *side tool*. A concave portion can be roughed with the gouge, and is often finished with it; but frequently it is finished with a *round nose*, especially in work of large diameter. These and some other tools act by scraping only. Hence, as scraping roughens up the grain, the object always sought is to do as much preliminary work as possible with the gouge, and take the merest film off with the scraping tools. Round nose and side tools are shown on page 4261, in group 22.

Hard and Soft Woods. The relative utilities of scraping differ in the practice of turning hard and soft woods. It is done much more extensively in the first named than in the second. The reason is that the grain of hard wood does not become roughened up nearly so much as that of soft timbers. This, of course, is not an argument in favour of scraping, when turning can be done by the gouge and chisel. But when work is of a highly ornamental character, and of large dimensions, as in much of that done on the face-plate, the risks of hitching are lessened by the use of scraping tools. The harder the wood, the more nearly the conditions approach to the turning of the softer metals. Thus, Spanish mahogany is harder than baywood, and lignum vitæ or box are more suitably scraped than beech or birch. Also, dry, well-seasoned woods can be more readily scraped than moist and spongy stuff. So that there is room for exercise of judgment. When details have to be turned to exact dimensions the scrapes are valuable aids, because very minute amounts can be removed by their assistance. The hardwood turners, therefore, have a large assortment of scrapes for turning concave and convex portions, for recessed work, right and left-handed, besides special forms of tools for internal shoulderings, etc., in some of which it would be quite impossible to use the turning gouge or chisel.

All turned work may be classified under two heads, that done *between centres* and *chuck work*.

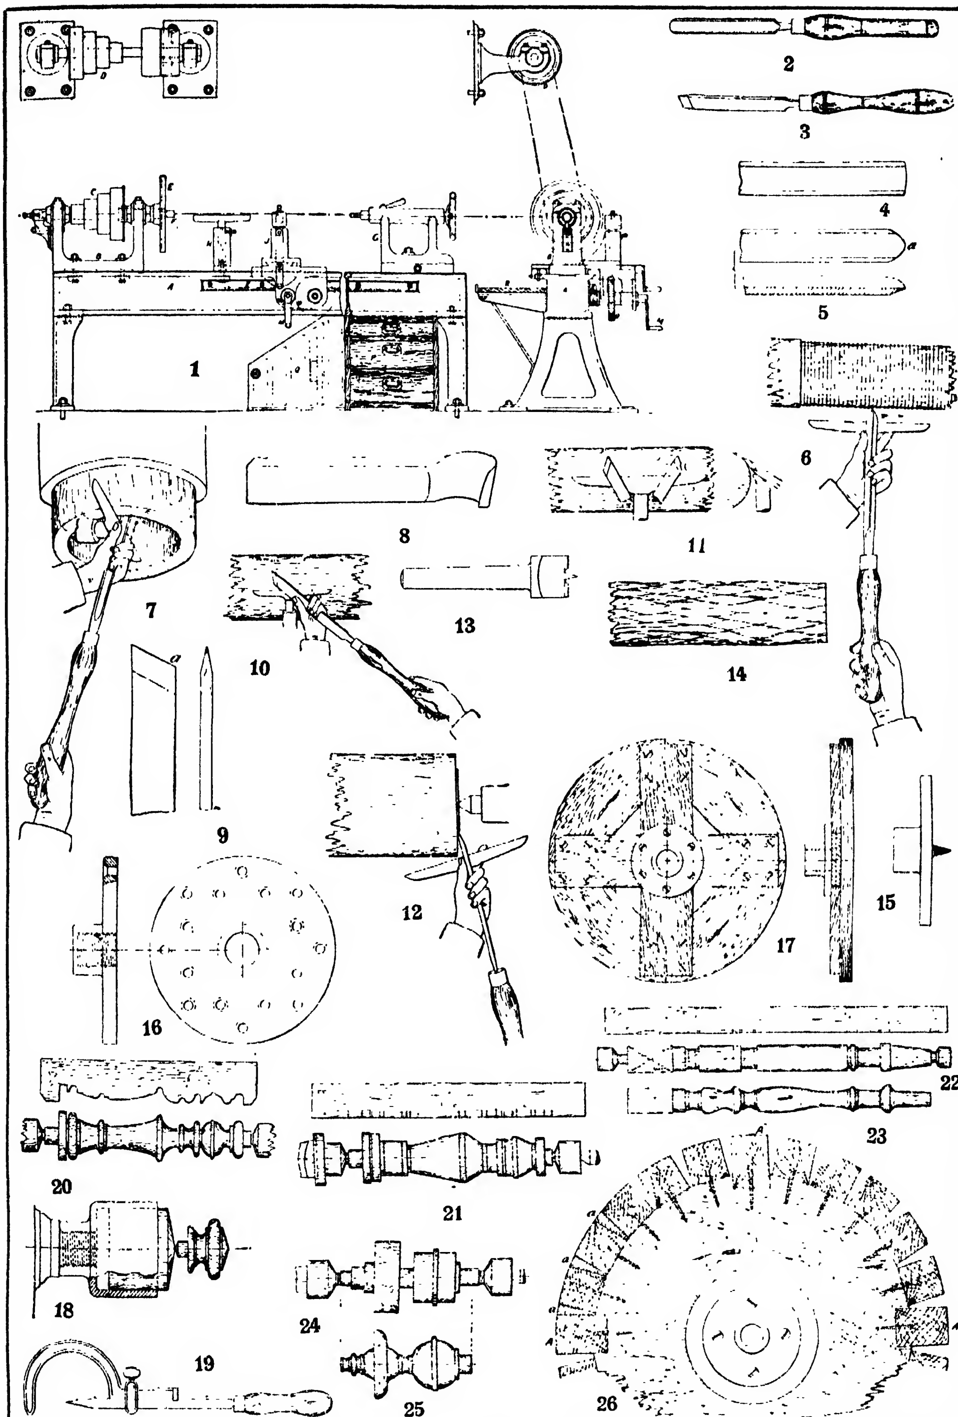
Work Between Centres. This signifies that the piece to be turned is supported and revolved between the fast headstock and the loose poppet. It includes all pieces the length of which exceeds the diameter by so much as to require support besides that afforded by the headstock. Generally, such pieces are held and rotated by the fork or prong centre. This is interchangeable with other chucks on the mandrel nose. It derives its name from its fork or prong-like character. The end of the wood, if soft, is driven against it, or, in hard wood, a saw kerf is often made to receive it. The back poppet centre is entered readily by screwing up the mandrel slightly. Occasionally other chucks are used to drive work between centres, but in most instances the fork is employed; 14 shows a piece of wood roughed out with the axe preliminary to turning.

Chuck Work. This signifies that pieces are held at the headstock end only, and without other support. Pieces the length of which does not greatly exceed the diameter, or which are of less thickness are turned thus.

Face-plates. These are the principal chucks. They differ from those for metal turning in their greater simplicity, comprising only two forms, in a range of dimensions. One is the *screw point chuck* [15]—that is, the work is held on it by a central, short, tapered screw, having a coarse thread. This is sufficient to hold a small piece of wood, say, not exceeding 4 in. or 5 in. in diameter. Thick blocks —say, above 3 in. or 4 in. diameter—are generally secured in addition with a couple or three wood screws put in from the back of the plate.

Large Face-plates. These [16] have countersunk holes for the attachment of work by wood screws inserted from the back of the plate. They are made in as large a range as the capacity of the lathe will admit. For very large face work, lathes are made either with a deep gap in front of the headstock, or the headstock is made to turn round through 90° or 180°, so that work can be taken as far down as the floor. In such cases a special rest is rigged up on a heavy *floor stand*, sufficiently massive to remain steady under the stress of turning. In many cases the trouble of reversing the headstock is avoided by carrying the mandrel out at the rear to hold the large face-plate, so that it is always ready for use. Pattern-makers, as well as wood-turners, use these face lathes for wheel work of all kinds.

Wooden Plates. The face-plates are made of iron, except in the very small sizes—say, under 4 in.—for which brass is commonly used. But a large proportion of turners' work, and much the largest in pattern turning, is done, not on the metal plates directly, but against an intermediary plate of wood screwed to the metal. The advantages are these: The wood plate can be faced up truly, while the metal plates often run slightly out of truth, due to wear on the thread. Turning can be done right up against the wood without inflicting damage on the tool edges. There is a slight elasticity in the wood, noticeable when turning, by comparison with turning done down close to the iron. But the principal advantage is that the wooden plates can be recessed to receive work for re-chucking centrally, often, too, without using screws, the friction of the work in its recess—or over a check standing out, in the case of chucking by a hole—being sufficient to retain it in place for light turning. In time, as a face-plate becomes turned down thus, a new one is substituted. Small plates are made of solid stuff; but those over 12 in. to 18 in. diameter are built up, the plainest with battens, the largest with a cross and diagonals [17]. Much work is chucked, not directly on the plate, but on blockings screwed to it. The reason is, that plates of several feet in diameter are rather expensive, and would soon wear out if frequently recessed. The face is, therefore, retained plane, and chuckings are done on



1. 12-in. centre wood-turning lathe 2. Turning gouge 3. Turning chisel 4. Turning gouge improperly ground 5. Turning gouge properly ground 6. Method of holding gouge 7. Finishing with gouge in hole 8. Slide rest roughing tool 9. Turning chisel 10. Method of holding chisel 11. Side chisel applied right and left hand 12. Side chisel cutting down an end 13. Finished article and its templet 21. Article as roughed out and strip marked out in lengths 22 and 23. Article roughed out and finished 24 and 25. Article roughed out and finished 26. Square turning

temporary blocks screwed to the face. This is done in large gear wheels, pulleys, and rings of various kinds.

There are some classes of turned work in which it is undesirable or inconvenient to insert screws, yet which must lie against a flat face-plate. Then *paper joints* are useful. These are adopted extensively in pattern turning, and it is surprising how great a mass paper will hold. Newspaper is suitable. It is glued on both sides, one side going next the plate, the other receiving the work. On large pieces, narrow strips of paper at intervals are sufficient; pieces of a few inches diameter may be carried with one piece of the same diameter. The joint is broken after turning by lifting the work with a chisel inserted in the joint, when the paper splits into two.

The Bell Chuck. The bell chuck is termed the *cup chuck* [18], and is used for some classes of work too small or too long for the face-plate, and also for pieces which have to be bored [7], or for objects that have to be turned and cut off in succession [18]. Boxes, egg-cups, vases, are examples of the first; drawer-knobs and cord-pulleys of the second. The wood is driven into the cup and holds by friction alone. The chuck is usually of brass.

There are many very delicate objects which will not bear any driving into the bell chuck, or into a wooden chuck driven into the bell, and recessed to receive work. For such objects the *spring chucks* are valuable. These are made generally in a hard wood, box being the best, sometimes also in brass. The body of the chuck, slightly tapered outside to receive a ring, is split by several saw kerfs cut radially nearly to the bottom of the chuck, and the metal ferrule is made to compress the body round the work by tightening it down the tapered body. Turners make these for their own use in several diameters.

Methods of Measuring. The diameters of turned work are mostly taken with common calipers. When large numbers of similar pieces have to be done the calipers are often fixed with a thumbscrew. A sizing tool [19] is also used with a guide at the back, for repetition parallel turning.

Dimensions in the longitudinal direction may be taken with a rule; but when quantities are done, a strip is generally used, having the various lengths marked across it, whence they are transferred to the work. In such cases the piece is roughed out approximately parallel to the largest diameters, and the lengths set off on the rotating piece. Then these are set in with the keen angle of the side chisel down to the various diameters, which are turned, and checked by the calipers. Every portion is first turned as a parallel section, after which the different moulding sections are shaped with the gouge and other tools. Compare 20 to 25.

Templets. These afford much aid to calipers in repetitive work. They are cut from a thin strip of wood and tried upon the work [20] from time to time as the final corrections are being made. A little chalk or red lead may be rubbed on the edge to indicate the localities where contact takes place.

Straight Shafts. When a long portion of turned work is to be perfectly straight, as in the shafts of columns and pillars, and in pattern pipe-turning, much time may be saved by first turning down at each end and in the centre to the correct diameter, and then planing a flat along from end to end, forming a tangent to the diameters. This, being chalked or red-leaded, becomes a guide to rapid reduction of all the intermediate portions, which can be turned almost to size without stopping the lathe. It is then easy to finish with a side chisel, and correct, finally, with a firmer chisel.

Steadies. When long, slender pieces are being turned between centres they wobble, and cannot be turned truly without support intermediate with the centres. These steadies are very plain by comparison with those used by metal turners. Sometimes a rigid rod only is wedged between the ways of the bed, to be kept in contact with the back of the work; but, generally, a block of wood or an iron bracket is bolted to the bed to carry either a vee-block or to receive semicircular blocks. A single vee-block will cover a moderate range of diameters, but semicircular blocks will fit only one side. The practice is to turn down a portion to the correct size, somewhere about the centre of the length; grip that with the steady blocks, and then proceed with the remainder of the turning. In very flimsy work the steady is shifted to two or three successive positions; or more than one steady is used. Lubrication is necessary, or the friction between the work and the steady will cause smoking, and char the wood. Soft soap is the best material to employ. If a lathe is fitted with a slide-rest, then a travelling steady which follows the work behind the tool can be used, as in metal-turners' lathes.

Square Turning. The principle of this is illustrated in 26. The articles to be turned are arranged round the periphery of two or more discs, which are driven between the centres, driving with a face-plate at one end attached to its disc, the other end being supported on the back centre. The pieces of wood are attached with screws, the lengths being in excess of the finished article, to allow of the portion with the holes to be cut off subsequently. It is not necessary to fill in the spaces between the pieces with a view to prevent breaking out of the grain by turning, but those who are not skilful in the use of the tools glue strips in, as shown at *a* in 26. The blocks, A, in the illustration are simply distance pieces, by which the end discs are retained rigidly. Of course, the larger the diameter of the ends the less will the slight curvature due to the radius be in amount, and generally such ends would have to be framed up with a cross and segments. After the faces have been turned corresponding with one position of the articles, they are turned round and re-screwed in successive fresh positions, until all four sides are finished.

Ornamental Objects. The work of the geometrical turner requires special high-class chucks, and a special lathe. But very beautiful, effective ornamentation can be produced by the plain wood-turner by the repetition of similar figures, such as those shown in 20 to 25, and allied forms, for there is no limit to the combinations of curves and straight lines which are possible. Vases, flower-holders, candlesticks, watchstands, work about overmantels, toilet-boxes, epergnes, and much beside, can be so made, or enriched with ornament. Much may be done by turning rings the cross sections of which are those of various geometrical figures, and cutting off arcs therefrom to form the tripod-legs for stands of various kinds, or for carved handles. These are turned on the face-plate, most figures requiring re-chucking; objects of square, circular, octagonal, or fluted sections can thus be produced by turning.

With regard to the finishing of woodwork, any of the usual preparations can be employed, according to the character of the wood and the work — brush varnishing, French polishing, lacquering, painting. Inferior woods may be stained previous to polishing.

WOOD-WORKING *concluded*

ADVERTISING

The General Avenues of Business Publicity. Mail Order Advertising. The Business of Advertising

Continued from page 6802

By WAREHAM SMITH

ADVERTISING is the art of creating a demand by publicity: it is to-day one of the greatest forces of commercial life, and it is no exaggeration to say that millions of pounds are spent annually in applying the power.

Advertising—the art of advertising—cannot be taught in the usual way. There are no text-books or acknowledged professors, and the attainment of a position in its ranks does not entail an expensive course of instruction or necessarily involve a long apprenticeship. The qualifications are a strong personality, a sound general education, and a keen perception. There is no business that offers greater advantages to the man who can see and grasp an opportunity.

We have said that advertising cannot be taught—nor can it. One may learn how to draw up an advertisement, what type to use, what space to buy, and how to buy it, and some useful hints are given in these pages on these points. You can learn a thousand and one things, useful and even necessary to know in the connection, but of themselves they are not advertising—they are not the *spirit* of advertising. It is the argument—the happy thought—the bright idea—the smart catch phrase—the power of perception—the insight into human nature, that sell the goods, and these things cannot be learned by rule of three.

Placing Advertising Business. It will be as well first of all to enter somewhat into the conditions of the advertising business. An advertiser wishing to inaugurate a campaign arranges details as to space, price, position, etc. (*a*) with the advertisement manager of the various publications direct; or (*b*) he employs an advertising agent to make the necessary arrangements; or (*c*) he places some contracts direct with the publisher, and some through an agency, as he may deem it expedient.

Generally speaking, the business is apportioned in the following way:

About nine-tenths of the total is done through advertising agents. The agents handle nearly all the business that is placed with daily newspapers. The monthly magazines accept a small amount of business from the advertiser direct. Of the advertising in the illustrated weeklies about 25 per cent. is arranged without the intervention of an agent. It will be seen from this that the advertising agencies play a very important part in the business, and their position in the field is rather a peculiar one for the reason that although they work ostensibly in the interests of the advertiser they receive their remuneration from the publisher. On all contracts placed by the agency the publisher pays a commission, varying generally from 10 per cent. to 15 per cent., according to the standing of his publication and its power to command business. Various other arrangements are often entered into between publisher and agency, such as an additional discount for cash or an extra commission if the business received exceeds a certain amount. There is no fixed rule, each publisher being a law unto himself in this respect, but 10 per cent. is the usual commission paid by first-class publications. The agency is responsible to the publisher for payment for contracts placed by it, and is regarded as a principal, all contracts being made as such, and not as an agent for the advertiser. The position of the agency is analogous to that of a man serving two masters, and although much controversy has arisen within recent times as to the efficiency of the system, still, as exemplified by first-class agencies, it appears to work satisfactorily.

The Advertising Agent. It is not perhaps of particular importance for present purposes to enquire into the inner working of an advertising agency, but it is at least relevant to the subject, and digression in this direction may not be uninteresting. The agency acts: (1) as space brokers—that is, buyers of space from the publisher on behalf of the advertiser; (2) as advertisement managers and advisers to the advertiser.

In either case the commission paid by the publisher is the same. Some agency businesses consist entirely of the former, some the latter—others combine the two according to the requirements of individual clients. Generally one of two methods is adopted by the advertiser in prosecuting his campaign: (1) The organisation of an advertisement department under the control of a man who combines a knowledge of advertising with a study of the exigencies of the advertiser's particular line of business, or (2) he places himself almost (in some cases *quite*) unreservedly in the hands of an agency. In the former case he makes such arrangements as will, in his opinion, ensure that his business will be properly and profitably conducted. His advertisement manager is generally a man with an extensive knowledge of the art of advertising. He has learnt from experience what to buy in the way of space, and the lowest rates at which it may be obtained. He designs copy, or has in his department experienced copy-writers, and, being on the spot, he has his fingers on the pulse of the business, and should be able to tell without loss of time when a publication or a particular advertisement fails to show a profit on the outlay. Almost invariably he employs an agency to act as space broker, to make the necessary arrangements with the publisher. By doing this he often saves time and money, the agency, acting for several advertisers, being frequently in a position to buy more cheaply; and, on the ground that service is not required in any other direction, the agency frequently comes to an arrangement with the advertiser concerning the commission received from the publisher.

Turning to the second method, the properly-equipped agency can and generally does render very important service to the advertiser, whether his outlay be large or small. It acts the part of an advertisement manager, and, in addition, brings to bear the experience gained by years of experimenting and observation made in the interests of numerous clients with diverse interests. The agency maps out the campaign, the publications to be used, advises as to buying space, and secures best positions possible. It writes the advertisement copy and

booklets; executes illustrations, and makes the process blocks; designs posters and sees that they are properly displayed; organises where necessary a follow-up system; originates selling schemes; checks accounts to make sure that the advertiser has received the space ordered and charged for, etc.

In addition to the business of space broker and advertisement manager to the advertiser, the agency sometimes undertakes the duties of advertisement manager to a publication—that is, it takes over the whole of the advertising space in the journal. This is known as "farming," and the financial arrangement is either a commission paid to the agency on the advertising revenue it earns for the publisher, or the payment of a fixed sum by the agency for a fixed amount of space.

These, then, are the conditions under which the business of advertising is conducted. A knowledge of advertising may be acquired in anyone, and applied to anyone. The defined tracks are—service with the advertiser, with the publisher, or, with the advertising agency. For service with an advertiser a knowledge of the following subjects is required: the writing of advertisements (technically copy-writing); conditions governing the buying and using of space in the press, and outdoor publicity; the buying of advertising material such as colour printing and show-cards; the weight of paper, etc.

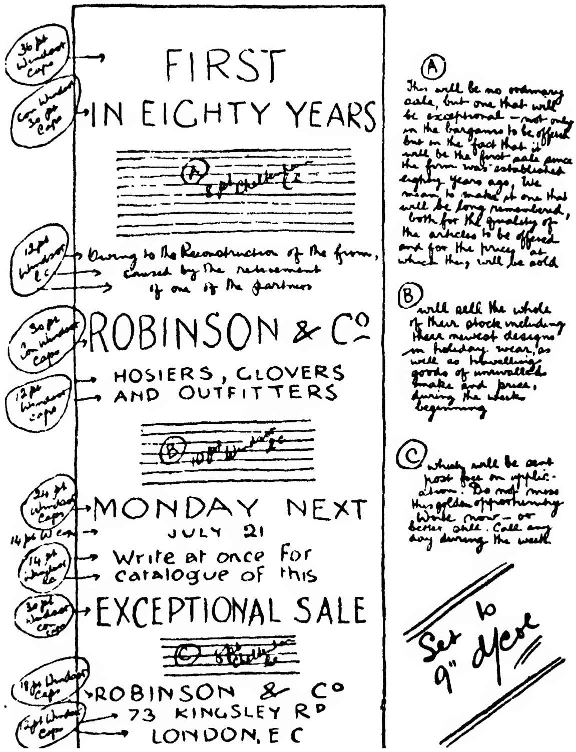
Copy-writing. The broad principles which must be followed, if advertising as a whole is to be successful, and a particular advertisement is to fulfil its purpose, may be stated as follows: an advertisement must (1) attract attention; (2) invite reading; (3) carry conviction.

Various devices are employed to arrest the eye of the reader. A distinctive border may be used with effect, but to rely on a border is to a certain extent a confession of weakness on the part of the text.

Pictorial blocks also find favour with many, but the picture which has no relation to the text is open to the same criticism as that applied to the distinctive border. If a block is used at all, the design should be an integral part of the advertisement as a whole. Such a block will serve a double purpose. It will arrest attention in the first instance, and will then fulfil the second requirement of a good advertisement by drawing the reader unconsciously to a perusal of the text. The same may be said of a pregnant and illuminative headline—a collection of words which gives, as it were, a slight mental shock to the reader, stimulates his curiosity, and makes him ask for more.

The Heading. To invite reading, as we have just seen, an advertisement must in the first place have a significant design or letter-press heading. After that, type-setting plays a very important part; excessive display should be avoided, and a generous allowance made for white space. Type of a smaller size set in an open manner will always present a more attractive appearance than type two or three sizes larger set so as to cover the whole space available. In order to sustain the interest of the reader the minor headings should, if possible, be made no less significant than the title itself. Up-to-date newspapers and magazines contain in their editorial columns excellent examples of the use of attractive cross-headings, which the advertiser who desires to give life to his advertisement will do well to study and imitate.

We now come to the most vital characteristic of a good advertisement. The announcement may be seen; it may be read; but if it fails to convince the reader of the merits of the commodity offered, and of the desirability of possessing it, all effort has been wasted. It is here that the art of the copy-writer comes into play. The qualities of good copy are so subtle that it would be hopeless to give any directions likely to help the aspirant. Suffice it to say that the best copy is clear without being wordy, terse without being obscure, eloquent without being extravagant.



1. EXAMPLE OF DUMMY ADVERTISEMENT

To write intelligently, an intimate knowledge of the article is required, its value from all points of view, what the buyer wants to know about it; and, equally important, what you want him to know. It should also be remembered that different subjects require different treatment; a motor-car cannot be advertised in the same way as a patent medicine. The public, too, vary in class and temperament, and a successful appeal to one class may prove a failure to another if the same point of view is taken.

The "Dummy" and its Uses. The copy-writer is furnished with particulars of the subject of the announcement and of the space allotted. His first duty is to rule off on a sheet of paper a diagram exactly the dimensions of the proposed

advertisement. This sheet, which should have a total area at least twice as large as that of the diagram, is known in printing offices as a "dummy." We shall assume that the copy-writer has drafted the text to his satisfaction, and that it now remains for him to adapt the text to the space before him. For the sake of simplicity we shall suppose that the advertisement will consist of letterpress only.

How to Make Headings Attractive. The main heading first claims attention. Sufficient space must be allowed to enable it to stand out clearly. White space should be left either on one side or on both. The heading which runs across

FIRST

IN EIGHTY YEARS.

This will be no ordinary sale, but one that will be exceptional—not only in the bargains to be offered, but in the fact that it will be the first sale since the firm was established eighty years ago. We mean to make it one that will be long remembered, both for the quality of the articles to be offered, and for the price at which they will be sold.

Owing to the Reconstruction of the firm, caused by the retirement of one of the partners,

ROBINSON & CO.,

HOSIERS, GLOVERS AND OUTFITTERS,

will sell the whole of their stock, including their newest designs in holiday wear, as well as travelling goods of unrivalled make and price, during the week, beginning

MONDAY NEXT,

JULY 21.

Write at once for Catalogue of this

EXCEPTIONAL SALE,

which will be sent post free on application. Do not miss this golden opportunity. Write now—or better still, call any day during the week.

ROBINSON & CO.,

73, KINGSLEY ROAD, LONDON, E.C.

2. ADVERTISEMENT SET UP FROM DUMMY

the full measure of space allotted is seldom effective. The secondary headings, in which doubtless other important features of the advertisement find expression, should next be considered. The probable distance between each should be calculated and care be taken that no two of them come too closely together. Should this appear likely to happen there is nothing for it but to alter the intervening text. The positions of headings or display lines being thus more or less settled, these headings may be sketched in on the "dummy," and the subsidiary matter, or, to give it a simpler term, the "story" may now be dealt with. If the story be a long one, any attempt to write it in the space left between the headings on the "dummy" will only give trouble to the unfortunate printer and result in typographical errors. A much better plan is to have it written separately, marked off in sections A, B, C, etc., the spaces in the "dummy" which each section is to fill being marked correspondingly.

The illustration [1] shows a "dummy" advertisement ready to hand to the printers, and 2 shows the same advertisement in type. At this stage the advertisement is known as a "proof." For instructions in correcting proofs, see page 4193.

Use and Abuse of Bold Type. The last point which falls to be considered is the choice of types. As a rule, this is a matter which may generally be left to the printers, if the copy is to be set in an office which is known to employ expert display compositors. It is a great mistake to insist on the use of bold type throughout. Bold type is all very well for headings, and even then it should be used with discrimination and in different degrees of boldness, otherwise one heading will kill the other. In the body, bold type should never be used except for one or two lines at a time which require special emphasis. The eye soon tires of following more than a dozen lines emphasised in this manner. For different styles of type, see article beginning on page 5026.

Some Devices of Display. The advertisement shown in "dummy" and in type is of the most straightforward character. The object has been merely to show the student how to prepare a simple announcement for the printer, and to initiate him into the more simple devices of display. These devices, indeed, are multitudinous in number. The rules and borders commonly found in a printing office can be employed in almost an infinitesimal variety of combinations. The art of creating new and original devices is a matter of experience, and not difficult to acquire. This leads us naturally to discuss the question of pictorial advertising.

Pictorial Advertising. The term "pictorial advertising," for convenience sake, will be regarded in its widest sense, being taken to include all designs used in advertising which have been created by an artist and reproduced by an engraver. A picture or design which has been reproduced by an engraver for printing purposes is known as a "block." In regard to the value of blocks in advertisements there is some difference of opinion. Certain successful advertisers rarely or never use them. Others, again, depend almost wholly upon an appeal to the eye rather than to the intellect—much depends upon the subject.

Varieties of Blocks. A block may be a reproduction of the article or articles offered for sale; it may be symbolical of some idea which is the main-spring of the advertisement; or it may have no relation to the text, being introduced merely to arrest attention. The first case is simple. The block should represent the article accurately, and without exaggeration, and too much emphasis cannot be laid on this point. The symbolical design or picture affords great scope to the ingenuity and imagination of the advertiser. The design which has no relation to the text is the least satisfactory form of pictorial advertising. It may serve to arrest attention, it is true, but it is quite possible that the reader who has been induced to turn from the latest news of the day to the contemplation of a picture of a beautiful woman may experience some measure of disgust when he finds in

the picture merely a device to bring before his notice some prosaic article.

Blocks in common use among advertisers are of two kinds—line blocks and half-tone blocks. For information concerning blocks and their making, see article beginning on page 6481. The advertisement student need not despair if he has no artistic talents—the actual drawing can be done by any artist. It is the *idea* in designs, as well as the text, that commands success.

Newspaper Advertising. With regard to the media in which the advertisement is to appear, the advertiser has an enormous choice—daily and weekly newspapers (London and provincial), and periodicals (weekly, monthly, and yearly); some popular, some devoted to a comparatively select few, others to given objects. The selection depends entirely on the article to be advertised, and the amount of advertising appropriation. Generally speaking, if the article is a popular one, the daily and weekly press are likely to prove the most profitable. This is evidenced by the attitude adopted by most advertisers to-day. Of course, if the amount at the disposal of the advertiser permits, he can go very much further afield, his only care in any case being to ensure a profitable return for his money. Newspaper advertising differs considerably from that of magazines. In the case of the former, it should be remembered that there are fewer and larger pages, and that each page carries a number of advertisements. The advertiser has the choice of an ordinary or preferred position, the latter being next editorial matter, and costs anything from 10 per cent. to 50 per cent. extra, according to the newspaper. Great care should be exercised with the copy intended for ordinary positions, so as to secure a contrast with other advertisements. Very much, indeed, depends on the intelligence of the printer or advertisement office clerk, as the ordinary position advertiser is not allowed to dictate just exactly where his advertisement shall appear on the page. Several successful attempts have been made to print half-tone blocks in newspapers, but the result, at the moment at all events, is not to be entirely relied upon, and more satisfaction can be obtained from line blocks. If a half-tone is used, the screen should not be more than 60.

At the beginning of a campaign especially large spaces are desirable. To the advertiser with a large appropriation and a popular article, they are always profitable. At the same time there are thousands of advertisers doing a good and steady business by the use of small spaces; much depends on the article—much more on the copy. The arguments in favour of newspaper advertising are, shortly: the price per thousand is low; the returns are quick; it covers an extremely large field; it allows of topical advertising.

Magazine Advertising. With regard to magazines, the chief point to remember is that the paper and printing allow of considerable pictorial effect, and this should be taken advantage of to the full. An artistic and striking design should invariably be used, and, other conditions being equal, the result is good. Here, again, it must be remembered that the advertisements are placed together, mostly at the beginning, and some at the end of the book. The front and back covers are obviously good positions, and one or two preferred pages may be had. If the advertiser can afford it, a whole page should be used, and a right-hand one if possible. The arguments in favour of magazine advertising are briefly: it has a long life; it has generally a home circulation; it allows of artistic pictorial display.

Outdoor Publicity. In this branch of advertising the field is very wide indeed, and includes bill-posting, omnibus and tram advertising, railway advertising, boardmen (commonly known as sandwichmen), signboards, and metal plates, window displays, circularising, etc. It is not within the province of these articles to indicate whether any or all of these forms of publicity are profitable. It *is* publicity, and must have some value to that extent, but the advertiser requires a long purse and much patience who invests his money solely in this form of advertising. As a matter of fact he rarely does. Here, again, much depends upon circumstances, and it is yet another instance of the fact that advertising is not "rule-of-three" work. Bill-posting holds the foremost place in outdoor publicity, and is here dealt with. It is unnecessary to go into details concerning the many other campaigns, as they are comparatively unimportant.

Bill-posting. Bill-posting is—and from the very nature of it probably always will be—a most difficult form of advertising to control, and for this reason it is apt to prove expensive. Posters, to be effective, require considerable skill, and no small outlay to produce—twenty thousand double-crown sheets (30 in. by 20 in.), in three colours, costing about £30 to print, in addition to which there is the designer's fee. The advertiser is at the mercy of the bill-posting men, and has, further, to take into account the vagaries of the climate, a bill often being put up one day and destroyed by rain and wind the next. Then, again, the employment of inspectors is generally necessary to ensure that the bills are in position. Much improvement has been noticed in recent years, however, as far as the human element is concerned.

Hoardings are owned by different firms of bill-posters in competition with each other. In London there are between fifty and sixty firms, but in the provincial towns the hoardings are held by one or two men only.

The charge to advertisers is based upon a fixed sum per week per double-crown sheet. This covers the cost of posting the bill (which, of course, is supplied by the advertiser) on the hoardings, and renewing it as often as necessitated by the weather. The rental varies from 1½d. per week down to ½d., and sometimes less. As the same price is generally paid wherever the location may be, it is obviously more profitable to the advertiser to pay greater attention to position than to price.

The most convenient size bills for posting in the United Kingdom are vertical 16-sheet and horizontal 8-sheet posters, the former being 10 ft. high by 6 ft. 8 in. wide, and the latter 5 ft. by 6 ft. 8 in.

Here, as in press advertising, the success or failure of a campaign depends very largely upon the design itself. Poster designing is a thing which an amateur should not attempt unless he combines art of a very high order with his knowledge of advertising. It should be remembered that very little in the way of argument is possible, the design must speak for itself; the passer-by has not always the opportunity, and rarely the inclination, for absorbing argument. What the poster wishes to convey must be conveyed at a glance or it fails in its object.

Posters are used generally to strengthen a press campaign, although instances occur where the advertiser relies solely on this form of publicity. A great advantage of the system is that advertising

can be localised, a consideration to the advertiser who wishes to concentrate his attention to a particular district—a theatrical enterprise, for instance.

Much valuable information regarding billposting and other forms of advertising is contained in "Benson's Facts for Advertisers," published by S. H. Benson, Ltd. (10s. 6d. net.)

Mail Order Business. Mail or post order trading is practised very much more extensively in America than in Great Britain, for one reason because the large shopping centres are far more widely distributed, and but for the mail order advertisers dwellers in remote districts would have to go without many little luxuries that they now enjoy. The system has much to recommend it to everyone but the local provincial trader, who views with some alarm the growing custom of his neighbours to spend money, perhaps hundreds of miles away, that would otherwise find its way into his till. The remedy, of course, is for the local trader to take up mail order trading. [See page 5930.]

The careful student of the advertisement columns of the press will have observed that the popularity of this class of business is increasing. To the aspirant to honours in the advertising field, therefore, the question of mail order advertising is of considerable importance, for, of course, advertising is the basis of the whole business. The watchword of the mail order advertiser should be "now," and his copy must convey that impression to the reader. "He who hesitates is lost," and many an order or inquiry has been lost to the advertiser because of the hesitation of the reader. Goods must be despatched "now," and inquiries answered "now."

Mail Order Advertising. There are three distinct features in mail order advertising—the advertisement; the catalogue; and the follow-up system. The aim of the copy should be, of course, to sell a certain article, or obtain applications for a catalogue. If a comparatively small space is to be used, one article only should be advertised. Particular attention must be paid to the block, which should portray the article in an attractive and pleasing manner, but with absolute truth. The price should be moderate enough to be on the face of it a bargain. Bear in mind that the object of the mail order advertiser is to cultivate satisfied customers—the selling of one article is a small matter—it is subsequent sales to which you will look for business. Every parcel despatched will contain a general catalogue, and such useful literature as you have prepared for the purpose.

The catalogue is the big gun of the mail order trader. It must be well got up, though not necessarily expensive. The blocks must be good and attractive, the type clear, and the arguments conclusive, the whole leaving in the minds of the reader a desire to buy. Bear in mind that you have severe competition from retail traders all over the kingdom. Bluntly, your object is to deprive him of his local trade, to bring that trade to a centre—your establishment.

On the tradesman's window depends much of his trade. Your catalogue is your window. See that it is well dressed. You cannot expect a purchaser to desert his local man without good reasons. See that those reasons are logical and clearly defined.

Save your customer as much trouble as possible; enclose simple self-measuring forms, if necessary, and always an order form, which should require very little filling up; also printed addressed envelopes. In addition to the catalogue, a nicely got-up brochure should be prepared, the object of which will be to interest the applicant for catalogues in yourself, your business, your methods, etc., with illustrations of the premises, different departments, staffs at work, etc. This will create a valuable personal impression. If the public do not know you, they will know *of* you, and it all helps to instil confidence.

The Follow-up System. The follow-up system is brought into use (1) to coax an applicant for a catalogue into becoming a purchaser; (2) to sell further goods to a customer already on the books. The card index system is the only successful method for the purpose [see page 6520]. Below is printed a suggested card for the former purpose.

CARD No. 1.

Name: THOMAS SMITH.
Address: 3, Wentworth Street, Leeds.

No. 1.	No. 2.	No. 3.	No. 4.	Remarks.
1/7/07.	8/7	15/7	22/7	

The card shows to exactly what use it should be put. The details can, of course, be altered to suit individual trades, the one given being intended to illustrate the method. The card should be kept under forward dates, so that as each date comes along the second or third follow-up can be despatched. For instance, the catalogue is despatched on July 1st, the date is entered on a card which is put into a date file under date July 8th. The date file is examined every morning, and July 8th is reached automatically. Follow-up letter No. 2 is then despatched, the date marked on card, which is then put forward to, say, July 15th, and so on. At the end of your system you will have either secured an order, or given the applicant up as hopeless.

Follow-up Letters. There are divergent opinions as to the length, number, and character of follow-up letters; but there should be no two opinions as to how they are turned out. The letters are a personal matter between the advertiser and his correspondent, and should be written in a personal strain—as a *letter*, not a circular. To be effective, it is well to let the recipient think that your message is to him, and him only. With the up-to-date mechanical appliances now on the market, it is a simple matter to type in a name and address to match the body of the letter. Above all, the signature must be an autograph. A print, litho, or rubber stamp deceive few people nowadays. The employment of a few girls to autograph letters will well repay the outlay.

The object of the follow-up letter is to establish personal relations—to put you on calling terms, so to speak. The letters must be consistent and continuous as to contents, and with increasing insistence, but not to the point of causing annoyance. Letter No. 1 is sent to cover catalogue, draw attention to the comprehensive character of the book, and suggest that recipient will find what he requires within its pages. In letter No. 2 trust that catalogue was safely received; assume correspondent undecided as to making purchase, although full particulars given of articles similar to that described in original advertisement upon which application for catalogue was made; dilate

a little on prices and quality, and hope to hear by return. In letter No. 3 express regret at not having heard; ask if there is any further information required; suggest as goods are seasonable lines will shortly be out of stock, and will not be replaced: that it is a good opportunity to test value given at the emporium, the cost of the particular goods being so small: the cold weather will shortly be setting in; has correspondent noticed the bargains in warm underclothing (or other topical allusion). In letter No. 4, after referring to correspondence, point out in strong sentences that goods are guaranteed to be as described, will be sent on approval—carriage paid; that you please thousands of customers weekly, and have no reason to think cannot please correspondent. Perhaps particular requirements are not listed; catalogue of other departments enclosed. Try another topical allusion.

The above are given to show the idea, and are probably more or less commonplace in themselves. The follow-up letter gives unlimited scope for the display of individuality, and on this quality depends the success of the attack.

Each successive transaction should be noted on card. These cards should be examined periodically to see if the customer has ceased to do business, and should this occur, as, of course, it must in time, a little follow-up series should be sent asking reasons, etc., and card should be taken from active file. This will avoid waste of postage, catalogues, etc., through sending to people who have removed.

CARD No. 2.

Name: THOMAS SMITH. *Folio.....*
Address: 3, Wentworth Street, Leeds.

	£	s.	d.		£	s	d.
3/8/07	3	2	6				
16/9/07	1	3	4				

Tracing Results from Advertising. This is technically known as "keying." A key is a special mark, appearing in the advertisement which, when answered, shows at once the medium which produced it, and it can be extended to show the particular copy used.

Presuming the name and address of the advertiser is W. A. Baxter, 14, Fenchurch Street, London, E.C., variations could be made as follows:

H. A. Baxter (a different initial for each paper), or—

W. A. Baxter, 14A Fenchurch Street (different letter to number), or—

W. A. Baxter, Dept. A., 14 Fenchurch Street (different department letter).

Different combinations can be used to distinguish particular copy. Every envelope containing an order or application for catalogues should be scrutinised for distinguishing signs, and a careful record kept in a book ruled as follows:

FOR CATALOGUE APPLICATIONS (left of book).

Date of issue.	Space of Advt.	Medium.	Copy used.	Number received.	Cost of Advt.	Average cost per application.	Subsequent value of sales at end of follow-up system.

DIRECT SALES (in right of book).

Number of sales.	Total value.	Average cost per sale.	Cost per £100 of sales.	Remarks.

A most reliable clerk should be placed in charge of the book, and the advertiser, or his advertising manager, should watch it closely. Directly a medium fails to produce profitable results, a strict inquiry should be made and, if necessary, the offending sheet cut off at once.

General Advertising. The advertiser who trades through the retailer invariably, at the beginning of his campaign, backs his advertising with a "selling" scheme in order to get his goods stocked. As a particular selling scheme is rarely used more than once, there is no object in dealing with the subject here. Such schemes can be thought out only after careful consideration of the conditions governing the particular trade in view, and the advertising man who can originate and carry through a good scheme is eagerly sought after, and commands a high remuneration.

At the beginning of a campaign the press advertising should be of an educational nature. A series of talks on the why and wherefore of the goods, written in good telling language, and set in plain, easily-read body type with little display besides the heading. The pictorial designs and fancy borders will follow after to serve as continual reminders. It should be remembered that designs consume much space, and only a little letterpress can be included—see that that little is good and to the point. It is impossible in the space at our command to give further specimens of advertisements, or examples of copy-writing. The student has the whole of the press before him to use as text-books, and a study should be made of the announcements put out by the many prominent advertisers of to-day. A habit of advertisement reading should be cultivated, and close study will soon indicate the line to be adopted.

To Obtain a Position. As in other walks of life, luck must enter somewhat into this matter. On leaving school, and especially if influence cannot be brought to bear, the young man is often obliged to take the first promising berth that is offered to him, but he can influence his destiny very much by continually being watchful for an opening elsewhere. If he has a gift for copy-writing little difficulty need be experienced. In these days copywriters are in great demand, but the work must show signs of genius to earn appreciation. A good plan is to study as far as is possible from the outside the business of different advertisers, and to submit the advertisement personally. The common mistake should be avoided of putting a price on one's work until it has been accepted. In the case of a mail order proposition the advertisements should be offered on the "no cure no pay" principle—that is, if the advertisements fail to produce results they are not to be paid for. An offer of this kind will create confidence, and should the designs be successful more will be requested.

THE STAGE

Broadly speaking, actors resemble poets in that their gifts come direct from nature, and only to a limited extent is their art a thing of schools. There are many critics, of course, who object entirely to the word "art" being applied to acting, and it is no doubt true that any art which relies so much on the physical personality of the artist is not entitled to rank high; but, with this limitation, a good case may be made for the art of acting. We have here, however, no space for academic discussion, and must confine ourselves to a very brief and practical consideration of the qualities necessary for success on the stage and the means whereby these may be brought into use.

The Efforts to Teach Acting. Schools of acting innumerable have had their little day and ceased to be, from Macklin's school, whence came Foote and Dr. Aaron Hill—who also tried to found an "academy"—and Sheridan's more ambitious, but more visionary, "oratorical academy," to the different projects associated with the name of the late Sir Henry Irving. Doubtless, long before Macklin and Sheridan, enthusiasts set up dramatic schools, and long after the present generation has disappeared enthusiasts of the future will be wasting their time at the same futile business. For there is no gainsaying that the only good school of drama is the stage itself. It is true that on the Continent dramatic teaching has long obtained, but the best judges are agreed that the methods of the Théâtre Français applied in England would do more harm than good. It is all in the best interests of English acting that the notion that an actor can be taught should be consistently discouraged. There is, perhaps, no calling for which the impulse must be accompanied by natural aptitude to the same degree as that of the actor; and we would have the aspirant understand, in the most unmistakable manner, that, lacking this, no amount of hard work, no amount of intellect, will help him to success; and, equally, possessing it, success is most elusive and less to be reckoned upon here than in any other profession, while, once secured, it is more difficult to maintain.

It is true that in the case of women, good looks and a commanding figure may help in these degenerate days to secure success on the stage. We have in mind at the present moment a lady whose name is familiar among the eminent actresses of to-day, whose photograph is vastly popular with collectors, who is never out of an engagement, and, beyond looking handsome, and walking across the stage with some degree of gracefulness, she is utterly destitute of the slightest dramatic ability. There are others in like case, and the serious student will have these awful examples always to remind him or her that there is something rotten in the state of the stage!

Adult Acting and Child-play. The natural gifts that are essential to good acting have been in the possession of each one of us, but we have not all succeeded in retaining them. The dramatic instinct is born in every human being; a great deal of child-play is essentially acting, and excellent acting sometimes. But most people, as they leave their childhood behind, leave with it the land of make-believe, become self-conscious, and cannot *at will* subordinate their own personalities to those of imagined characters, which in childhood they had done almost as an act of faith. The actor has to be consciously unconscious, so to speak; he has *consciously* to imitate the gestures and attitudes which, in a child, are the result of no artistic effort; he has to be as "natural" as the child by means of consummate art; he has to *appear* to believe in fictions of the brain in which the child actually *believes*. This faculty, which is far more rare than people are apt to think, is somewhat vaguely defined as "dramatic instinct." It follows, therefore, that a technique of acting can only begin by assuming the presence of this faculty, and in its absence all is vain.

The Essentials of Good Acting. Assuming that the aspirant has dramatic instinct, which involves a natural feeling for the display of emotions, a ready sympathy for the distinguishing traits of character, and the power of expressing feelings with some dramatic conviction, there remains much that may be done by study, and something also by instruction, in order that the dramatic talent may be developed to the fullest extent. Lloyd, in his poem, "The Actor," very justly observes:

> "To this one standard make your just appeal,
> Here lies the golden secret: LEARN TO FEEL.
> Or fool, or monarch, happy or distrest,
> No actor pleases that is not *possessed*."

But even so, the poet points out further on that feeling is not enough:

> "The player's province they but vainly try
> Who want these powers—Deportment, Voice,
> and Eye."

That is to say, having derived from nature the great and essential gift, one must turn to art for the means of applying that gift to the best advantage.

The Actor must "Feel" His Part. Perhaps feeling might be given forty points, and all the other qualities together, sixty; but feeling is precisely the quality in which the ruck of our actors are deficient. It alone can give intelligence and consistence to the reproduction of a character on the stage or the interpretation of a sequence of emotions. "I cannot simulate suffering without an honest sympathy with it," says Mrs. Bancroft. "I hold that without great nervous sensibility no one can act pathos; it is impossible to feel the sentiments one has to utter, and but half the author's meaning can be conveyed. It is a casket with the jewel absent. The voice in emotion must be prompted by the heart, and if it is 'out of tune, and harsh,' why, then indeed, the voice is 'like sweet bells jangled.' Art should help nature, but nature must help art." The celebrated actress puts the matter very clearly in these words, which indicate that a deep and abiding interest in one's fellow-creatures is an essential characteristic of the good actor.

Studying Others and Ourselves. "The proper study of mankind is man," and assuredly this is a maxim that must ever be in the mind of the actor. Not only must he study and sympathise with his fellow-men, but, as Lewes remarks in his classic on acting: "We are all spectators of ourselves; but it is the peculiarity of the artistic nature to indulge in such introspection even in moments of all but the most disturbing passion, and to draw thence materials for art." This is well illustrated in the confession of Talma, the great French actor, when he says: "I have suffered cruel losses, and have often been assailed by profound sorrows; but after the first moment, when grief vents itself in cries and tears, I have found myself involuntarily turning my gaze inwards, and found the actor was unconsciously studying the man, and catching nature in the act." It is thus that great acting becomes possible. A tailor's dummy or a dressmaker's model would be quite sufficient to study for many of the actors and actresses who cumber the English stage to-day.

Given great natural gifts of sensibility, a rich, passionate nature, strong sympathetic voice and expressive features, but above all an utter absence of self-consciousness, it is surprising how physical defects may be overcome. Many famous actors, such as Betterton, Garrick, and Macready, triumphed thus over physical inequalities; but a pleasing personality is also greatly to be desired, though beauty of feature is by no means essential, as it is notorious that most of the great actresses have been plain women: and in the strong light of the stage a plain woman often looks better than one who is naturally beautiful. This, however, touches the question of "make-up," at which we shall arrive in due course. Of first importance after the qualities we have already mentioned is the art of speaking. It is doubtful if there is a people, other than the Americans, who speak, on the whole, more slovenly than we English do. Speech is an art that has been all but neglected among us. Here, our stage is immeasurably behind the French stage, and this is one of the elements of the actor's art that can be taught.

Elocution or Effective Speech. Some there are to whom a clear and effective manner of speech, with a good range of voice, which almost unconsciously they can pitch to suit the hall or theatre they are speaking in, has come as a direct gift of nature. But they represent a very small minority, and it may be taken that most aspirants to the stage or platform, however good their natural speaking voice may be, would be the better for a thorough course in elocution or voice production. Into the matter of elocution the personal equation enters so largely that it is not possible to lay down any hard and fast rule which would be of equal service to all beginners. That might be done, and has, indeed, been done, with some measure of success in a long treatise, but nothing can quite take the place of a course of study with a master, who is watching every characteristic of the student, correcting his faults and leading him gradually to the full exercise of such powers as he possesses. Provided the student is already endowed with the histrionic qualities enumerated above, a course of voice-production might with advantage take the place of the ordinary lessons in elocution, as there is a tendency in the latter to leave the student with some mannerisms acquired from the master, and this, unless it is strenuously resisted, may be disastrous.

While we are all for the "natural" in acting, it is imperative to remember that natural acting is not the mere reproduction of everyday speech and gesture. Heaven forbid! Shakespeare's plays hold the mirror up to Nature in a way that is at once the admiration and despair of all modern dramatists; yet his characters, throbbing with human passions, are made to declaim their emotions in blank verse such as no human being ever spoke in actual life. Here is the poet's art; he enthralls us with the beauty of his diction and the reality of his creations. So should the actor aim at perfection in his speech, which, carefully studied and polished, will bear no absolute resemblance to the ordinary speech of daily life, but will yet, by its charm and natural delivery, produce in the audience the agreeable feeling that it is "true to life."

Importance of Emphasis and Pause. After having understood his author—which is, of course, the first duty of the actor—he must next make clear his author's meaning, for, as Tennyson says, "Words half reveal and half conceal the soul within." A word may be made to convey just as much or as little as the speaker determines; hence the need for him to know precisely what he wishes it to convey. Thought must precede and regulate the utterance. "Emphasis and pause," says Lewes, "are, indeed, the supreme difficulties of elocution. They are rarely managed by those who read blank verse, even in a room, and on the stage the difficulty is greatly enhanced. Nevertheless, no one can pretend to be an actor of the poetic drama who has not mastered this art, although in the present day it is like many requisites, badly disregarded, and we hear the noblest verses spouted (not spoken) with the remorseless indifference of the actor who announced himself thus: ''Tis I, my lord, the early village cock!'" Colley Cibber also observes justly that "the voice of a singer is not more strictly ty'd to time and tune than that of an actor in theatrical elocution."

Life and Spirit of Good Speaking. Canon Fleming, in his excellent treatise on "The Art of Reading and Speaking," illustrates very effectively the importance of proper emphasis thus: "On the right management of emphasis depends the very spirit and life of good speaking. If no due emphasis is placed on any words, not only is our speaking heavy and lifeless, but there is no intelligent meaning thrown into what we speak or read. Let us take a simple question: 'Do you ride to town to-day?' These six words are capable of no fewer than four different meanings. If pronounced thus, 'Do *you* ride to town to-day?' the answer may be, 'No; I intend to send a messenger in my stead.' If thus: 'Do you *ride* to town to-day?' the answer may be, 'No; I intend to walk.' 'Do you ride to *town* to-day?' 'No; I intend to ride into the country.' 'Do you ride to town *to-day?*' 'No; but I shall do so to-morrow.' Thus the whole force of an expression may depend on a word, and we may give our hearers quite different views of the same sentence by placing the emphasis differently."

It may be thought that these niceties of detail are scarcely necessary where one has mastered the sense of the words to be spoken, but that is as great a mistake in acting as depending upon "the inspiration of the moment," which Lewes very happily likens to trusting to a shipwreck for one's first lesson in swimming. Perhaps the crowning difficulty of elocution, which nothing but constant practice will overcome, is the need to be slow while not seeming slow, "to speak the phrases with such

distinctness, and such management of the breath, that each shall tell yet due proportion be maintained," as hurry destroys all effect, and is the hallmark of the incompetent actor. Even Garrick in his early days had not attained proficiency here, and, having failed to study his breathing, came near to spoiling his greatest scene on his first appearance. On the whole, we urge the aspirant to stage honours to make a most careful study of voice-production.

Gesture on the Stage. Following the mastery of the art of speaking, and intimately associated therewith, is the consideration of gesture. Here, again, our national characteristics have to be overcome, as there is so little natural grace in the gestures of English people that on the stage actors are apt either to be deficient in gesture or to overdo it. Hamlet's address to the players is the supreme classic of advice on the subject, and there it will be remembered the actor is advised to "suit the action to the word," but equally "the word to the action." He is also warned against excessive gesticulation in these words: "With this especial observance, that you o'erstep not the modesty of nature; for anything so overdone is from the purpose of playing." A visit to almost any London theatre to-day will show that, impeccable though Shakespeare's advice undoubtedly is, surprisingly few have profited by it. The annals of the stage from Betterton to the present day are full of stories illustrating the errors of even great actors in the important art of gesture. When one reads, for instance, of the extravagances of Quin, it is difficult to understand how he came by his reputation.

Even Garrick never quite conquered the art of "repose on the stage," and Macready only achieved it by the most rigorous training, such as reciting violent scenes from Shakespeare's tragedies with his arms bandaged, so that his tendency to overgesticulate might thus be overcome. "The easier an actor makes his art appear, the greater must have been the pains it cost him." Let all aspirants bear these words of Macready in mind. We have seen many books illustrated with numerous diagrams purporting to teach the whole art of gesture, but we cannot recommend any, and, except certain rules for walking upon the stage, which may be imparted to the student or acquired by him from observing graceful actors, there is nothing that can be set down in writing beyond the words of Shakespeare: "Let your own discretion be tutor," and "do not saw the air too much with your hand." Of course, all exercises of the limbs, such as calisthenics and dancing, should be undertaken by the would-be actor, as they tend to impart grace and suppleness of the body, and if there is an intelligent mind controlling that body, the result cannot help being satisfactory.

Costume and "Make-up." We come now to the question of making-up, but can only touch upon this in the briefest possible way, as nothing but experience gleaned from "old stage hands" will help in the details. It is an art in which the modern stage is vastly in advance of the days of Garrick or Macready. Actors of our generation have largely thrown off the traditions that used to rule in the matter of costume and make-up. For generations Shylock was played in a red wig. Edmund Kean was the first to break this tradition, which originated from the belief that Judas was a fair Jew. Macready was probably the last to observe the old custom of wearing a plume of feathers, long thought to be indispensable to the leading figure in a tragedy. The red wig still lingers in the make-up of the country bumpkin, but, broadly speaking, the stage is now rid of all stupid conventions in the matter of costume, education and travel having made such inappropriate dresses as Garrick wore in Shakespearean parts and foreign characters quite impossible. Thus, in the matter of costume no advice beyond the dictates of common sense and historical accuracy is required; but in the make-up of the face there are still many actresses, though chiefly those of no importance, who require to be reminded of these words written by the late Lady Martin (Helen Faucit) many years ago: "When the skin is covered with what is in fact a painted mask, the colour, which, under strong emotions would come and go, is hidden under it, and the natural expression of the countenance destroyed."

Prospects of Success. Having every qualification for success on the stage, the aspirant may still find himself faced with nothing but failure. As already hinted, it is not always genuine ability that leads to success, but we have not the space here to deal with the varied causes which make the life of the player a greater lottery, and, on the whole, a source of less satisfaction than that of any other professional. The theatrical world swarms with undesirables, with harpies, and with sharpers; and the path of the aspirant is, in consequence, full of pitfalls. The real tragedies of the stage-door are often as poignant as, and infinitely more numerous than, the mimic tragedies of the stage. We can, therefore, only advise aspirants to act with the greatest possible caution in any dealings with "theatrical agents," and to endeavour rather to get into touch with the managers of provincial companies.

The Best Fields for Aspirants. Time was when the avenue to success was clear and unobstructed to all who had the talent. That was in the old days of the stock companies, when in all the large towns theatrical managers employed permanent companies of actors who could support any "star" from London in whatever repertory he or she chose to give the local playgoers. These stock companies, and the old "circuits," were the training ground of the Victorian stage, and produced many of our most famous actors, not a few of the "older hands" of the present day having graduated from them. But, unhappily, the modern system of flooding the provinces with "touring companies," that merely give imitations of London successes, has ruined this most excellent training ground for the stage. An actor of very limited ability can pass muster for a few years, and possibly have an enjoyable life meanwhile, as an intelligent parrot, repeating to provincial audiences imitations of London acting; but this is not training nor experience worth having for the serious aspirant, and in the end it is a very poor life indeed. There are a few repertory companies, such as Mr. F. R. Benson's and Mr. Ben Greet's most excellent Shakespearean and "old comedy" companies, that provide the young actor with a good substitute for the stock companies; and proof of the value of such companies, which tour the provinces with considerable repertories, changing their bill almost every night during a fortnight, is seen in the fact that many of the leading actors on the London stage to-day have been trained in these repertory companies. It is to companies of this kind, where, instead of playing the same piece for three years on end, the young actor will have constant and refreshing change of parts, that the aspirant should direct his attention. Needless to say, the amateur dramatic society is a most useful first step

in the direction of a stage career, and enables a person of sense and sensibility to ascertain whether or not he has any aptitude for the art.

We cannot but confess that, if asked to advise anyone on the adoption of a stage career, the person of discretion with knowledge of the theatrical life is bound to say that if one can find profitable occupation in any other branch of work, one would do well to leave the stage severely alone, and to young women this applies with especial emphasis.

Playwriting. Here we can only touch very briefly on the subject of playwriting, as it is not at all probable that any student of the SELF-EDUCATOR will look to it for assistance in the writing of a play. Although we have many examples to the contrary, there is little doubt that a practical knowledge of the stage is of great importance to the dramatist. Mr. Pinero, Mr. Jerome, Mr. Brandon Thomas, and many other successful dramatists, have begun their careers as actors. It is worth while remembering that many of the Elizabethan dramatists, including Shakespeare himself, were actors also. The ability that makes of a man a successful novelist might be of very little value to the making of a playwright; but the income that can be earned by a popular dramatist is so great that there are few novelists of note who have not made a bid for stage success, and not one in a score has succeeded. If one has the ambition to write stage plays, it would, therefore, be well to secure some practical knowledge of the stage in any sort of company as a preliminary step. But so far as the actual writing is concerned, we fear that only a laborious study of published plays—classic and modern—will help to a mastery of technique, and after that there is a pressing need of some original inspiration. Given the latter, one might succeed even with bad technique, but without it the best technique in the world could not prevent failure!

THE BUSINESS SIDE OF AMUSEMENT

By ALGERNON ROSE

The degree of enjoyment is governed by the capacity to appreciate. Thus, the habitual theatre or concert-goer in a city becomes more and more critical. He is not content unless the performance possesses artistic excellence. In small provincial towns people are less fastidious, and audiences welcome less accomplished performers. Great talent, as long as it draws, may, in a big town, demand its own terms; but mediocre ability must take what it can get.

Acrobats. The term acrobat applies chiefly to equilibrists, contortionists, and trapezists. Since 1894, the law in England has prohibited the training of children as acrobats before the age of sixteen, except by their own father. Trainers, in consequence, have removed chiefly to Brussels and Antwerp. There, children of tender years are put through many cruel exercises in order to give abnormal flexibility to their bones and muscles. Acrobatic talent often runs in families. The members will practise perseveringly together and work at certain tricks for many years before exhibiting in public. This has been the case with the famous Craggs—the father, who was self-trained, teaching his five sons and one daughter many extraordinary feats.

There is as much difference between an ordinary tight-rope dancer and such finished performers as the Craggs as there is between a "pianist" who "vamps" an accompaniment and Paderewski. While the remuneration in one case may be 5s., in the other £50 a night may not suffice. In this class of entertainment, certain names stand out above all others, even as those of a few musicians appear as Tritons amongst thousands of struggling minnows. There were possibly many acrobats able to balance themselves as well as Blondin. He was recognised—they were not. In like manner Leotard could ascend and descend an immense spiral, balancing himself on a large ball. He obtained a vogue, and a consequent bigness of salary which others failed to get. Amongst many clever jugglers with inanimate objects we find the personality of Cinquevalli eclipsing that of his rivals, and his dexterity in accomplishing the apparently impossible exciting the interest of vast multitudes.

Trapeze Work. When we come to trapeze work, the names of the Leamys are remembered everywhere. Although the safeguard of the net has made such performances less dangerous than they were, emulation has increased proficiency. The best trapeze work of to-day excels that of twenty years ago. Trick bicycle riding, balancing on the back in Japanese fashion, equestrian feats, and strong-man business, if remunerative, depend not alone on perseverance, daring, and ability to do what is undertaken, but on the gift possessed by the performer, or leader of the troop, to convince those who give engagements that the entertainment offered will attract powerfully and more than justify the terms demanded. The "management" of a hall have an unsympathetic way of regarding art. They estimate the precise amount in cash that each turn will "draw." This applies equally to the greatest concert performers. From a business point of view, Caruso or Melba are "good for" so much. It is a mathematical problem. Reckoning 21 in. as the space each person in the house will occupy, if a certain star will "draw" a specified number of people, and the auditorium "holds" a given sum, the fee to leave a tangible profit cannot exceed a certain limit unless a larger building is taken and a greater risk incurred.

Advertising. It is well known, in dealing with the commercial side of amusements, that the cleverest artist frequently possesses least aptitude in financial negotiations. If he gets big terms he is indebted for them to the ability of his agent. Where, however, as in the case of Sarah Bernhardt or Adelina Patti, artistic and commercial talent are almost equal, the way in which the former is aided by clever réclame considerably enhances in public estimation the status of the individual. The study of the public performer who receives big fees is how constantly to attract the notice of those who pay willingly high prices for admission. Such is the contrariness of human nature, that it is a truism to say, "Once convince the public that they cannot get into an entertainment, and they will clamour for admission." But it should not be forgotten that if inadequate ability is "boomed" unduly, it frequently means disaster to the artist.

To turn to early engagements, the young professional, if without other means, must contrive to live by fees received from pupils. Without experience as a teacher, he cannot at first demand his own terms. Yet, the axiom, "do as you would be done by," should be remembered. It is not chivalrous to declare that a neighbour's system of teaching is wrong and to offer instruction at half-price. When there are other children not being taught, it is despicable to "poach on the preserves"

of a fellow professor by underselling him. In past years professional jealousy has done much mischief to the interests of musicians as a body. To counteract such tendencies, the Incorporated Society of Musicians was formed, membership being confined to properly qualified candidates. In many ways, the society is most helpful to those embarking on a career. The young professional, therefore, cannot do better than seek election as a member. It will bring him in touch with the right people, and differentiate him from certain bogus teachers who advertise lessons at 2s. 6d. a course, or 3d. each. They are dear even at that sum.

To make a beginning, it is advisable to have a neat circular printed and sent to the most likely addresses given in the local directory. More effective than printed matter is, however, personal recommendation. In return for assistance given at charitable performances, the clergyman, organist, or other officer of the place of worship attended by the young musician, can often assist him materially. In order to get one's name into the programme and become known, there need be no scruple in offering to assist at a boná-fide charitable entertainment. At a time of life when the enthusiast is most impetuous it may be difficult to wait in hope of engagements to come; yet it is waste of energy to badger acquaintances in a tactless way.

Getting Known. The young professional should be contented with a little at first and devote his energies to practice and composition rather than spoil a favourable impression he may have made by declaiming against those who happen to be more fortunate than himself. If, presently, he obtains two pupils a day at 2s. 6d. an hour they will bring him in 30s. a week. This is more than many a young physician, after a far costlier training, earns in the first or second year of his professional life. The physician may not advertise any more than a member of the Stock Exchange; but the musician has no such restriction. Nevertheless, he must be careful not to indulge in any advertising which looks vulgar. If he desires, ultimately, to win the favour of cultured people, he must strive to keep up the dignity of his profession in all that he does.

The biographies of most of the great virtuosi show that before becoming famous they had to go through the drudgery of teaching unmusical pupils, however galling it may have been to them. As a rule, the life of the great executive artist begins with teaching reluctantly. But it ends with imparting experience whole-heartedly to pupils of his own choice. Keen on getting recognition, the talented young singer or player endeavours to procure a minor engagement in a company making a provincial tour. This may be fixed during the summer vacation, when the company may visit various seaside resorts. As his pupils are then taking holiday, permanent teaching will not be lost.

Touring. As with theatrical touring, a concert tournée requires good health on the part of every member of the company. If the tour is to pay, to get from one town to another in a given time may necessitate frequent night-travelling. Sometimes, on arrival at a destination, it may be necessary to proceed immediately to the concert-room without a meal. If the rough is taken cheerfully with the smooth, and the manager of the tour is honest, when it is ended unpleasantnesses will be forgotten and the change remembered happily.

During a tour the young musician should collect carefully any favourable allusions to his performance in the local papers. Printed subsequently as "Opinions of the Press," such testimony will carry more weight than the most conscientious self-praise, or even certificates won at a music school. Possessed of a number of newspaper notices, his plan—if he is a solo singer or instrumentalist—is to send his circular to the secretaries of various societies, in the provinces or London suburbs, mentioned in the Musical Directory (Carte, Berners Street, W.), in which he should be careful also to have his name entered. Personal appearance being of equal importance on the concert platform as on the theatrical stage, it is customary to have a photograph printed on the front of the circular. These may be taken also to the music shops or music publishing houses, the latter being requested to send professional copies—if the musician is a singer—of any songs they wish made known. It is the experience of publishers that, if a new song is encored at a concert, its sale is increased. For that reason the services of a good singer are recognised by the payment of a small fee for each public rendering. The singer forwards copy of the programme as a voucher.

Paying for Appearances. The pressure of young artists to obtain a hearing in a limited number of influential concerts is nowadays excessive. Ambitious performers, possessing private means or well-to-do friends, have become, therefore, easy victims of unscrupulous concert agents. By this it is not inferred that all agents are dishonest. Those of reputation, who act on behalf of established favourites, seldom concern themselves with artists seeking recognition. But a new and less scrupulous "Concert-Direction," on being established, will often send circulars to young musicians requesting a visit. A critical hearing is given, as well as sympathetic advice. It is pointed out that to hide such light under a bushel is wrong. To achieve success a concert must be given, to which the musical critics will be specially invited. The agent undertakes to hire the hall, engage attendants and artists to assist, to print tickets, programmes, and see to the advertising. An estimate is given. If beyond the means of the aspirant or his friends, the sum is reduced. A substantial deposit being paid in advance, the concert takes place.

As space is valuable in the daily papers, the critics do not attend. Minor journals may insert paragraphs supplied by the agent, or even detailed comments. These are of little worth. According to the gullibility of the victim, so is the length of the bill. The artists who have assisted, and whose fees are specified in a lump sum, may, individually, have paid for the privilege of appearing. Yet, in a business sense, the agent may have acted honestly in regard to the items for the hall, printing, and advertisements In any case, the money is lost so far as the artist himself is concerned. Whether at bogus or boná-fide concerts, the system of paying for appearances is wrong. Conspicuous talent, providing that it exists, cannot for ever remain unrecognised.

The Theatre. Successful theatrical speculation involves considerable capital. The actor-manager, who takes the financial responsibility upon himself, has an exceedingly anxious time. Not only have suitable premises to be leased and staffed by a small army of workers, but if the piece put on is a new one and musical, unless the manager has a will of his own, what with the interests of the librettist, lyric writers, composer, singers, and actors to consider, little progress will be made. When we hear of one artist receiving £100 a week, another £70, and another £60, it may surprise the

amateur to be told that, on the authority of a London magistrate, well acquainted with the subject, an actor's average is not more than 35s. a week. What many members of the profession, therefore, desire are "smaller salaries and larger incomes." It is, of course, better to receive 35s. a week regularly than to play in a piece at £30 a week which runs less than a month, the cost of dresses being deducted from salary, and, after rehearsing gratuitously for six weeks, "resting" the other ten months in the year. For rehearsals there is no pay. These sometimes go on for months. In a few London theatres salaries are now paid during the last fortnight.

Opera Companies. One opera company advertises that chorister-pay per week is for tenors, £2 7s. 6d.; baritones and basses, £2 5s.; sopranos and contraltos, £2; extra salaries being given for small parts played by the chorus.

To many aspirants such terms may appear attractive. It by no means follows that the amounts advertised will be received. When a personal trial is given, the manager may consider the quality of voice, or ability to act, falls short of his standard. In certain choruses, instead of receiving salaries, novices have to pay for appearing in minor parts to get experience. In a West End theatre a stage manager (not actor-manager) may get £10 a week for much hard work, having to be in the theatre from early morning till late at night. The stage-carpenter will probably receive £3 a week. This he supplements by perquisites; otherwise there might be no limelight to spare for the lesser stars. In certain theatres the conductor of the orchestra receives £12 a week. Daly's band alone costs over £200 a week. Some of the players in this band possess violins valued at more than £50 apiece. A West End box-office keeper receives £6 a week, and his assistant £3. Programme-sellers and cloak-room attendants get 3s. a night, and the supers 1s. 6d. In the provinces half West-End prices are paid. The aspirant who has taken part in amateur theatricals and become stage-smitten finds the glamour dissolve when coming to the practical side of theatrical life.

The Dramatic Agent. Engagements are solicited through the dramatic agent. His office in London is either in the Waterloo Bridge Road, a turning out of the Strand, or in the purlieus of Shaftesbury Avenue. The hours are from 11 a.m. to 4 p.m. Contingents of unemployed, sometimes in poorest attire, wait their turn to hear if engagements can be found for them. On a name being entered, a small fee is paid. If an engagement results, 10 per cent. or more is charged on the first year's salary. Without interest, the chance of getting into a good touring company is nil. All that can be hoped for is that the tour will be genuine. There are few actors who have not experienced being stranded a long distance from home in their early days when a tour has collapsed. If the company is boná-fide, an engagement, including travelling, seldom yields more than 30s. a week. Out of this, board and lodging have to be paid and sometimes dresses provided. In case of illness no margin remains. There may be a fatiguing journey in the morning, a rehearsal in a strange place all the afternoon, prior to the performance the same night. After that it may be necessary to search for lodgings, unless these have been secured in advance. Add to these troubles the rivalries and jealousies of stage life, and it is a marvel that "mumming" should continue to attract so many victims.

Pantomime. The manager relies chiefly nowadays on scenic and spectacular effects. Large sums of money are lavished on the mise-en-scène, often at the expense of the salaries of the majority of the company, just as, in grand opera, the chorus may be starved in order to provide big fees for a few stars. After long gratuitous rehearsals, ladies of the ballet receive 25s. a week. But their dancing is not comparable with the highly-trained terpsichorean skill of the prima ballerina, whose salary will be £30 or £40 a week. The principal boy may receive £10 a week. The first clown will probably get £20 a week, the harlequin and pantaloon receiving £5 each, whilst an ordinary knockabout has 30s. The harlequinade, which used to be the chief pantomime attraction, is now relegated to the end. In the days of Joseph Grimaldi, his genius brought the clown into great prominence. Since his time there have been no men of similar ability in his line, and the clown no longer draws in the same way.

Music Halls. A comic singer, doing three or four halls a night will receive, according to his ability, from £10 to £40 a week. From this he has to deduct the hire of a conveyance from one theatre to another. Only exceptionally gifted artists command their own prices. Dan Leno, working four halls a night, made over £200 a week, but the excitement killed him. A well-known serpentine dancer in ever-changing colours received £20 a week. A troupe of good acrobats may get £50 a week, whilst débutants who have not yet made a name, may only receive £7 between a troupe of seven. A wrestler will get about £20 a week, as well as a purse, if successful. Unknown performers are paid nominal sums on short contracts, and are put either at the beginning or end of a programme. Should the "turn" score a success, they are then at liberty to demand higher fees and receive longer agreements. As long as they are capable of drawing the amount asked, the management is not likely to let them go elsewhere. After some years of minor engagements, a husband and wife, making a prodigious "hit" in so-called "thought transference," are receiving £500 a week because they draw more than that sum.

Circuses. Whether in town or country, the chief care of the circus manager is his stud of horses. These are often of great value. An intelligent performing horse may be insured for £1,000 or more. Besides these, the manager has always a plentiful supply of daring riders. As there is an excess of young men desirous of breaking their necks in public, the fees paid are not high. The English horseman, being superior to most foreigners, it is often possible to get more lucrative engagements on the Continent than in this country. Here the riding-master may get £5 a week; principal equestrienne, £20 a week, and the principal horseman, £30.

Conjurers. West End ticket agencies or libraries do considerable business during the season in supplying all sorts of artistic talent for bazaars, juvenile parties, or social functions. As a rule the agent deducts 10 per cent. as his commission from the fees paid. Sometimes an agent will make an exclusive arrangement for the services of an artist who cannot himself obtain engagements. A clever conjurer known to the writer found it to his advantage to make such a contract with a firm in Regent Street. A brougham was in waiting for him every evening. During the fashionable season he was driven off to different aristocratic houses. There he gave a two hours' entertainment of sleight of hand, ventriloquism, and so forth. After having supper, he was driven home. For this he received

£6 a week. Beyond drawing up his programmes, he had no correspondence to attend to.

In this case, when charging a fee of ten guineas for a performance which cost only £1, the agent often made a big profit. Nevertheless, the entertainer was contented with his bargain. He had no expensive premises to maintain, and although skilled in his peculiar way, had no ability to make negotiations direct. So far as he was concerned, as long as he was in good health and able to entertain, he had a sure income of over £300 a year. If his agents occasionally made a large sum, it was their speculation and not his. But between the conjurer of average ability, who may get £1 a night, and a phenomenal prestidigitator like the late Mr. Bertram, whose fee for a single appearance sometimes exceeded £20, there are many intermediate stages of skill.

Dance Music. The fee paid to an agent for a lady pianist for four hours is usually 9s. 6d., with 2s. per hour afterwards and travelling expenses. In other words, she may get a fee of 7s. 6d. plus 1s. 6d. extra for every hour, and her rail or 'bus fare. A man pianist, for the same work, is charged by the agent £1 1s. and cab fare. This probably means for him 15s. for the night. A trio, consisting of violin, cornet, and piano, is usually charged £3 3s. for the night. Quadrille bands cost £1 1s. for each performer.

Concert Promotion. Whether the event be a concert, lecture, dance, or other entertainment, the cost of organisation is first governed by the necessary payments for hiring the hall and adjoining rooms. In municipal buildings, the hall-keeper has a graduated list of charges. For a public meeting of ratepayers, the hall is free. Special reductions are made if the entertainment is in aid of a local charity. On the other hand, for a gathering not coming under these headings, full prices are charged. The cost may vary from £1 1s. for the use of a small room during the afternoon, to £10 10s. or more for the large hall arranged for a concert. Proprietary concert halls have their own scale of fees. The highest charges are usually for an all-night ball. This necessitates the hall being cleared beforehand, and the floor specially prepared. Two guineas may cover cost of printing tickets and programmes for a dance. If light refreshments, or a sit-down supper, are included, the catering is estimated at so much per head. When fixing the price of tickets, the cost of the band must also be considered. Refreshments should be provided for the latter. In other entertainments, the fees of the artists constitute the main items to be defrayed.

Concert promoters should remember that all performers should be given their fees before they leave. The money should be enclosed in an envelope and handed over by the treasurer or secretary, a voucher being signed as receipt. Where several performers receive different fees, enclosing the latter saves unnecessary jealousy. Prompt payment also, after a professional performer has done his best, is more satisfactory than to be told that his "cheque will be sent on."

Lectures. Lectures, either grave or gay, by celebrities well known in the literary world can be arranged through various lecture agencies. The fees paid range from £1 1s. to £10 10s., and expenses. If the lecture is illustrated, and an oil lantern is required, it will cost £1 1s. extra. With limelight, the fee is £1 11s. 6d. A pianist may also be required. Where cinematograph exhibitions are given, the apparatus and attendants will probably run into £5 exclusive of travelling expenses.

OFFICIALS IN SPORTS AND PASTIMES

By Ernest A. Bryant

Cricket and football are essentially the sports of the masses. The development of the attractions of football is one of the most striking features of latter-day outdoor life.

The Professional Footballer. Some thousands of men of varying skill make a livelihood from football, but if a man means to be a professional footballer, he must make up his mind to devote the whole of his time to the game.

Under the rules of the Football Association, the maximum wage to be paid to players is £208 per year. The actual period over which play extends is only thirty-five weeks in each year. Football in public begins on the first day in September, and ends on the last day of April. For seventeen weeks in each year the player has his time to himself, except that in the early days of August he is expected to be within reach of his club to begin training for the first match of the season. Until a few years ago this limit in the wage-earning power of the player did not exist. Men were paid as much as £500 a year in actual wages, to say nothing of the gratuities given for the winning or drawing of matches. It proved in practice that the clubs could not maintain the pace which they had set. Football finance had become one huge gamble. At the end of one season clubs, hoping for success in the following season with the big "gates" which this would mean, bid high for players, and found, too late, that they could not support the liability to which they were committed.

In addition to the £208 per year which a man may receive in wages, he is entitled also to a benefit match after he has served his club for five seasons. This may amount to anything from £100 to £1,000, and so considerably increase the average of his earnings. Only one other payment is permitted: the player on signing an agreement to serve a club is entitled to a gratuity of £10.

The Start. To a man of sound physique, good health, and average agility, the way into a football team of repute is not difficult. Nothing, in fact, is easier, provided he have the qualifications, for football, like cricket, is one of the spheres in which the demand for first-class men always exceeds the supply. A player takes to the game, because he likes it, while a boy. Generally he begins as a forward. If he has not speed enough for that position, or finds that it is more to his taste to spoil the game of another player than to take the initiative in attack himself, then his place is at half-back. Centre half-back is the position at which a man should aim. In that place he must be equally ready with either foot, and this gives him such command of the ball and players that he can take either wing at a moment's notice. He has to accustom himself to placing the ball with accuracy to his forwards, to take a shot at goal himself, or to drop back to the assistance of the men in his rear. He is the pivot of the whole team. The man with a particularly good kick will adapt himself to the full-back position. He must be alert and courageous, and as little prone to nervousness as possible.

From a junior club the player will go to one of better calibre, and soon find, if he has any real aptitude for the game, that openings in still stronger sides are available. Many men have made their entry into First League football while still in their teens, and represented their country in international

matches before their twentieth year has been reached. The trainer of a football team is generally an old player. He looks after the physical training of the men during the week, travels to and from their matches with them, and, in a rough-and-ready way, acts as first-aid in the case of an accident on the field. For a really educated trainer, with a sound knowledge of anatomy, dieting, and rational exercise, there should be a good opening. Many trainers of teams are retired professional pedestrians, whose system of training is wholly wrong when applied to footballers, whose need is speed with endurance. A good trainer can command from £2 to £4 a week. The secretary of the club is generally team-manager. Recently it has become the custom to appoint old players of good reputation to this office, with a clerical assistant to keep the books. The secretaryship of a good club is worth £5 per week. At the end of his playing career—which may extend over ten to fifteen years, the footballer may hope for an appointment as a *linesman*. For this he receives half a guinea a match in addition to travelling expenses. This appointment, if satisfactorily discharged, leads to his engagement as referee, in which he is paid a guinea a match, sometimes two, as well as train fare and hotel expenses.

Cricket. It is less easy to succeed in cricket than in football, for the reason that there are fewer first-class teams. Good men are always wanted, but they cannot produce the necessary ability. There is a vast difference between high-class club cricket and the cricket which even a moderate county side plays. A man who scores hundreds regularly for his local club, or takes half a dozen wickets for next to no runs every Saturday afternoon, may be a hopeless failure on appearing for his county. Men like Hutchings of Kent, and Rhodes of Yorkshire are few and far between. They stepped full-fledged experts into county cricket. With the average man the process is long and arduous. Experience proves that only one man in a hundred can bowl as well as bat. Therefore it is as well, perhaps, that the aspiring player should develop that game for which he has a natural inclination. If he bowls naturally, he had better bowl; if batting be his forte, let him practise batting. But there is this reservation: no man should cultivate one phase of cricket to the entire exclusion of others. The good batsman must learn to bowl sufficiently well to take his turn as a change bowler. Hundreds of matches have been won by the man who goes on to bowl a new style of ball when all the regular bowlers are weary and unable to dislodge a "stone-walling" batsman. Hayward, A. O. Jones, Quaife, the late J. T. Brown, and many other examples will come to mind.

No man should presume to send in his record to his county club until he has made himself a master of fielding. He should model his work in the field upon John Tunnicliffe and Ranjitsinhji, for the slips; upon Jessop, Ernest Jones and Denton for mid-off and mid-on; and upon William Gunn and Victor Trumper for the long field. These men are worth their places in any team for fielding alone; they not only score runs themselves, they prevent their opponents from doing so. And that is the whole aim and art of cricket.

Cricketer's Fees. Thus equipped, the young player at the end of the summer sends in a record to the secretary of his county club, giving his average in batting and bowling for the season. If he be worth a trial, he will either be permitted to play in the following year in one or two of the less important matches, or will be appointed to a place on the ground staff. In the latter case he will bowl for practice games, and members of the club will reward him for skill, assiduity, and courtesy. When he becomes a regular member of the eleven he will receive, on an average, £5 per match, out of which he will have certain expenses to meet. Every time he scores a given number of runs, or takes so many wickets, he will be entitled to what is termed "talent money," while he may be sure that a specially good performance will then and there result in a subscription on the ground. He should average £200 a year from his cricket, while his benefit match will be worth £500 with a team like Warwickshire, or if the man be a Hirst—which does not happen to be likely—he will realise as much as £3,000 from teams like Yorkshire or Lancashire.

Handsome additions to the cricketer's income result from private engagements to "coach" 'varsity or other players, from schools, and from private clubs. When his playing days are done he may be appointed an umpire, for which he will receive a guinea a day. Many men have retaining fees from the M.C.C., to earn which they must play in matches, and make an occasional appearance at Lord's ground.

Gymnastic Instructors. The gymnastic instructor is a man always in demand during the winter. He should be still more in demand. As a rule, however, the instructor is content to follow where others have led. The man who hopes to succeed in this line must be prepared to initiate new schemes for gymnasia. He must, of course, be master of bars and boxing; must be able to show something new with the Indian clubs; invent new exercises with dumb-bells, and have the true eye and supple wrist for single-stick and foils. Army men hitherto have made the best gymnastic instructors, but too often they have preserved the same old system year after year, and killed the interest of their pupils. The man who knows his work will be always devising ways and means, not only of maintaining, but of increasing his membership. A prosperous club can afford to pay him £2 or £3 a week, which sum he will increase by private lessons to nervous or backward pupils.

Billiard Players. The billiard profession is very much envied by young men who can make two or three "twenties" in the course of a game of "a hundred-up." The life is not a pleasant one. Very few succeed. Such harvest as is to result must be gathered early in life, for the vitiated atmosphere in which billiards is played does not make for protracted possession of undimmed eyes and nice touch. The man who succeeds has, as a rule, begun his career in a billiard saloon as a marker. This is the last occupation to be commended. It involves long hours in a bad atmosphere, and temptations to intemperance and gambling. Still, the youth who has an aptitude for the game, and is thoroughly steady, can make a good living in this manner. His salary, which may be anything up to £2 a week, does not matter. His presents prove of more importance. By steady practice he qualifies for match play. He enters the Markers' Handicap, perhaps, or meets privately another player. As soon as his reputation becomes noised abroad he is invited to appear in exhibition matches, and when he qualifies for games in London he may make his thousand or more a year. Once his name is made he can earn a great deal of money by teaching billiards. On the whole, the calling is one of many risks and few successes.

THE PUBLIC LIBRARIAN

The Genesis of Free Libraries. The Work of the Librarian. Classification and Cataloguing Systems. How to Become a Librarian

By WILLIAM ANDREWS

THE popular library movement in England goes back only to the middle of the eighteenth century. It was not until 1753 that the British Museum was founded. It was the outcome of a bequest of Sir Hans Sloane, who left his extensive collection of objects of natural history, works of art, books, to the nation subject to the payment of £20,000, two-fifths of its original cost. The Government accepted the offer, and raised the purchase money by means of a lottery. Other collections of books, including those belonging to the English monarchs from Henry VII. to George III., were brought together and formed the library of the British Museum, which is now one of the leading libraries of the world.

The Genesis of Public Libraries. Before the passing of the Public Libraries Acts there were several important free libraries in various parts of the country, the chief being the noble library founded in 1653 by Sir Humphrey Chetham at Manchester. After much opposition, Mr. Ewart got a Bill through Parliament for the establishment of free libraries and museums of art and science, together or separately, in municipal boroughs of England. The Act was a somewhat restricted one, and was extended somewhat in 1855 by another, which remained in force until repealed in 1892 by an Act which provided for the adoption of the Libraries Act by appeal to the ratepayers.

In 1893 an amendment to the Public Libraries Act of the previous year was passed enabling all urban authorities, save the London parishes, to adopt the Libraries Act without an appeal to the ratepayers.

Other Acts have been passed, but they do not affect the main principles, or materially assist the working of the free library movement.

The great usefulness of free libraries is now being fully recognised, and there can be little doubt that in the immediate future their power and usefulness will be extended. In addition to meeting the more popular requirements of a lending library of good and wholesome literature, provision is made for juvenile readers, for getting them early interested in reading, and for helping forward school studies. Reference libraries are formed, containing the best books in various branches of knowledge. In most instances the best and latest technical works are procured, especially those relating to the trades of the place. Collections relating to local history and topography are usually garnered in this part of the library. Provision is made for the student to work with pleasure and profit.

Selection of Books. The formation of a library is by no means an easy matter, and in doing this, where a large number of books is required for a reference library, the librarian usually prepares lists of works covering various branches of learning, and submits them to two specialists in each branch for approval and amendment. Local requirements have much to do with the selection. One point to bear in mind is to have the best books of an author instead of all his works.

Equal care should be taken in selecting the books for the circulating library. Good books which the people will read with pleasure and profit should be placed at their disposal. A library must be kept up-to-date, and to enable the librarian to do this he should read carefully the reviews in the "Athenæum," "Academy," "Spectator," "Saturday Review," "Bookman," the "Times," and other critical journals, as well as watch the advertisements of publishers. The librarian and those under him should know something of the *inside* as well as the *outside* of books, so that when required they may be able to advise those in search of information.

It is customary to invite tenders for the supply of books, and care must be taken that prompt delivery is made. The readers should have new books in their hands as early as possible. All orders should be given in writing, and a copy taken in a copying press. When the books arrive they should be checked with the invoice, carefully collated, not only as regards pages, but also maps and plates. Then those requiring cutting should receive attention. Next the books must be stamped with the library stamp.

Then they are entered in an accession register, and afterwards in the stock-book, which contains a list of all books going into the library. This book should be kept in a fireproof safe. In the event of a fire, it will be required when making a claim on the insurance company. It also shows at a glance the money spent on books. The stock-book should give the following details: Date when the book was admitted, title, author, number of volumes, date published, class, vendor or donor, published price, cost price. Other particulars are sometimes given, such as size, style of binding, etc. It is customary in some libraries to give some of the details indicated above at the back of the title page.

The book is now ready for location on the library shelves. It is entered in a public library in its number in the Cotgreave or other indicator, which is a simple and useful means of recording the issue and return of books. Shelf lists of all books should be kept as a ready means of checking the stock of the library.

Classification. It is not an easy matter to classify books, and some thought and study must be exercised before it can be done in a satisfactory manner. In past times little care has been given to this subject, but to-day librarians are alive to the best methods.

That more generally adopted is the Dewey system, planned by Mr. Melvil Dewey, of the State Library, Albany, New York. By this system knowledge is divided into ten main classes, as follow:

0. General Works.	5. Natural Science.
1. Philosophy.	6. Useful Arts.
2. Religion.	7. Fine Arts.
3. Sociology.	8. Literature.
4. Philology.	9. History.

These classes are subdivided to any extent in tens, as decimals are the simplest means of dealing with figures. The plan of this system has thus been

explained: "5.537 means Class 5, Natural Science; Division 5, Geology; Section 3, Economic Geology; Sub-section 7, Mineral Waters." This seems complicated, but it is really a very simple and elastic system, and is now largely used in both large and small libraries.

Mr. Charles A. Cutter, another American librarian, has a somewhat elaborate system, too elaborate to be extensively employed. It is known as "Cutter's Expansive Classification." He employs the 26 letters of the alphabet to indicate his classes, and the second letter to mark his subdivisions. "This second letter," says Mr. Cutter, "divides each of the 26 main classes into 26 parts, and then a third letter divides each of these 676 divisions into 26 parts, or over 18,000 in all, taking the single letter, the double letter, and the triple letter classes together." Anyone wishing to study this system must consult Mr. Cutter's published tables.

English Classification Systems. A really excellent and simple system was invented by two experienced English librarians, Messrs. J. H. Quinn and J. D. Brown. Books are divided into 11 main classes, as follow:

A. Sciences.	F. History and Geography.
B. Useful Arts	G. Biography.
C. Fine and Recreative Arts.	H. Language and Literature.
D. Social and Political Science.	J. Poetry and the Drama.
E. Philosophy and Religion.	K. Prose Fiction.
L. Miscellaneous.	

"In each main class," says Mr. Brown, "the class letter alone is given to general works covering the whole, or a considerable portion of the subject matter of the class at large. Thus 'B' would mark all the general treatises or dictionaries on the 'Useful Arts,' 'G' general collections of 'Biography.' It has not been thought advisable to make an elaborate system of sub-divisions and sub-divisions, but simply to number in one sequence of even numbers each sub-class or division in its order. This enables the class of most books to be easily expressed by the plain notation of a letter or figure or two—G2, B30, F196, etc. The odd numbers are reserved for fresh divisions of the main classes, and it is thought that this feature will be useful in most libraries where new subjects are continually cropping up." Mr. Brown's "Manual of Classification" must also be studied.

Alphabetical Classification. The London Library is large and well planned. The system adopted is as follows: The books are arranged in broad divisions; that is, History in one division, Theology in another division, and so on. History is divided into one large alphabet. Abyssinia, Arabic, Egypt, England, France, etc., follow each other in alphabetical order. All books in these subdivisions are in alphabetical order under the author's name. This rule applies to all divisions. Theology is one large alphabet of subjects—Bible, Bible Commentaries, etc. Learned societies form one large alphabet, each society being placed under the first word of the title of the society. Periodicals are shelved in a similar manner; fiction under the names of the authors. Biography is one large division under the subject of the biography which brings all the lives of one man together. Miscellaneous subjects, such as Agriculture, Anatomy, Art, Motor-cars, Science, Political Economy, Zoology, are arranged under their respective subjects in alphabetical order in one large division named Science.

It will be gathered from the foregoing systems that a librarian must know something of many subjects to enable him to decide in which class to place a work.

Cataloguing. The compilation of a catalogue is, next to the selection of books, the most important part of the work of a librarian. Before starting one a careful examination of the better examples of catalogues should be studied. The compiler must regard his catalogue as the key to unlock the store of knowledge in his library. It must be simple and concise, but sufficiently full to indicate the nature of the book named. In many libraries used by the more cultured classes, the classified system is employed, and librarians, from experience, know how difficult it is to use by anyone except a well educated person. The dictionary catalogue is now the most popular and the most useful. This catalogue supplies names of authors with lists of their books, the titles of all books, and the subjects under different headings, all arranged in alphabetical order. The contents of some books must be briefly indicated. Numerous cross-references must be given in respect to authors' pen names and real names, and where writers change their names. In short the facts given should enable a person to obtain from a library the book or information required. In addition to printed catalogues, card catalogues should find a place in every library, and be kept up to date. The information on a card may be fuller than in a printed catalogue. Various books deal with this important part of library work, and must be carefully studied, and especially well-compiled catalogues.

Education and Examination. The Library Association, founded in 1877, and incorporated by Royal Charter in 1898, carries out a useful work in teaching and holding examinations, and granting diplomas. Summer schools are held in various parts of the country, and practical lectures are given by experienced librarians. Correspondence classes are also conducted. Particulars may be obtained from the secretary of the Library Association, Whitcomb House, Whitcomb Street, London. The course of training is as follows:

(a) Study in various prescribed subjects, namely: literary history, elements of practical bibliography, classification, cataloguing, library history and organisation, and practical library administration.

(b) Examination in each subject, and the writing of a satisfactory essay upon some aspect of each subject.

(c) Practical experience of not less than twenty-four hours a week, for at least three years, as a member of the administrative staff of one or more libraries approved by the council of the Library Association.

The candidates may study as they think proper, but to gain the full diploma their preparation must include the examinations, the prescribed essays, and practical experience. The "Library Year Book" contains all details of examinations and long lists of books to be studied. According to the regulations, "candidates for the full certificate or diploma of the Library Association shall have passed the examination in each of the six sections, and, if required to do so, a further oral test. Each candidate shall be required to make application not later than March 1st in each year to the Hon. Secretary of the Education Committee of the Library Association asking to be granted the diploma. The application must be accompanied by: (1) A thesis on some topic previously

SCHEDULE OF EXAMINATIONS FOR LIBRARIANS

Age Limit.	Examining Body, Time and Place of Examination.	CERTIFICATE EXAMINATION.	Fees.
None.	Library Association, Whitcomb House, Whitcomb Street, Pall Mall East, London, S.W. In May annually, in various parts of Great Britain and Ireland.	Examination in each subject, and the writing of a satisfactory essay upon some aspect of each of the following subjects: (1) Literary History; (2) Elements of Practical Bibliography; (3) Classification; (4) Cataloguing; (5) Library History and Organisation; (6) Practical Library Administration. Practical experience of at least twenty-four hours a week for three years as a member of Administrative Staff of one or more Libraries approved by the Council of Library Association.	None.
		DIPLOMA EXAMINATION.	
		Each candidate to make application to the Honorary Secretary of Education Committee of the Library Association asking to be granted the Diploma. Application to be accompanied by— (1) A thesis on some topic previously set by the Council. Notice of this topic will be given in the January number of the *Library Association Record.* (2) Certificates showing that the candidate has satisfied the Examiners in each of the sections of the Examination. (3) A Certificate, approved by the Council, showing that the candidate has worked for not less than twenty-four hours a week for at least three years as a member of the Administrative Staff of one or more Libraries. (4) A Certificate, approved by the Council, showing that the candidate possesses an elementary knowledge of Latin, and of one modern foreign language. The Examiners decide if it be necessary to subject the applicant to an oral examination.	

set by the Council. Notice of this topic will be given in the January number of the "Library Association Record." (2) Certificates showing that the candidate has satisfied the examiners in each of the sections of the examination. (3) A certificate, approved by the Council, showing that the candidate has worked for not less than 24 hours a week, for at least three years, as a member of administrative staff of one or more libraries, and (4) a certificate, approved by the Council, showing that the candidate possesses an elementary knowledge of Latin, and of one modern foreign language.

A youth entering a library should master "A Primer of Library Practice for Junior Assistants," by G. L. Roebuck and W. B. Thorne. It not only gives advice of a practical nature, but suggests a good course of reading. All persons engaged in library work should cultivate neat and plain writing. This is a most important matter, for he who writes well among the assistants in a library usually gets the more important work. In addition to the use of the typewriter there is much to be done with a pen. It is to be regretted that more attention is not paid to teaching writing in schools.

How to Obtain a Situation. Situations for youths in libraries are usually advertised in the local newspapers. It is, however, a good plan for a person having a taste for library work to write a letter to the chief librarian in the town in which he resides, asking to be put on the list of applicants for a situation. He must state his qualifications, say where educated, and get a testimonial from his schoolmaster, or clergyman, or minister. Boys in the larger public libraries start at 6s. per week, and at the age of 21 are paid about 25s. per week. If he has made the best of his opportunities he may expect to take charge of a branch library or discharge the more important work in the library, or become a librarian of one of the many smaller public libraries, and work his way into a leading position. Librarianship is by no means a well-paid profession, but it is pleasant and improving. Salaries of chief librarians range from £100 (or even less) to £1,500 per annum. The hours worked are not long, generally about 48 hours per week, but often the assistants are engaged when others are on pleasure bent, and this circumstance often leads to unrest. A man to be a successful librarian, useful to others, and happy in his work, must have a real love of books, and know their contents, and be of use to those seeking information. The ideal librarian should be a many-sided man, know something of everything, and everything about something.

Those engaged in library work often have their tempers tried by people who have no consideration for others, and are lacking in good breeding. It is difficult to deal with such people. We must remember if they are rude we must not sink to their level, but do our best under trying circumstances. The chief librarian should set his staff an example, and they will not be slow to follow his lead.

Bibliography. The following books cover the work connected with a library:

Chambers & Fovargue. "Law Relating to Public Libraries and Museums, and Literary and Scientific Institutions," 1899.

Library series, 5 vols.: "Free Library," by Ogle: "Library Construction," by Burgoyne; "Library Administration," by Macfarlane; "Prices of Books," by Wheatley; "Essays in Librarianship," by Garnett.

"British Library Year Book," 1900-1, by Greenwood.

"Guide to the Choice of Books," by Ackland.

"Abridged Decimal Classification," by Dewey.

Library Association series: "Handbook and Library Appliances," by Brown; "Public Library Legislation," by Fovargue and Ogle; "Public Library Staffs," by Cowell; "Public Libraries," by Greenwood; "Care of Books," by Clark.

Concluded

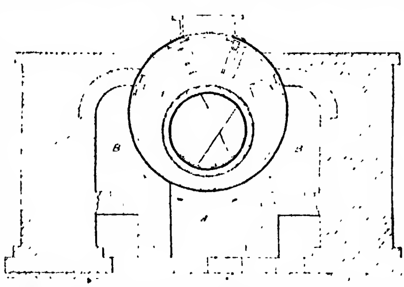
STEAM BOILERS

Classification. Horizontal Boilers. Cornish, Lancashire, Galloway. Multi-tubular, Marine, Locomotive, Vertical, and Water-tube Boilers. Combustion

By JOSEPH G. HORNER

THE function of a steam boiler is the generation of heat, apart from the engine in which the heat is to be utilised. It is a far cry from the earlier boilers, which carried steam pressures of only 3 lb. or 4 lb. above that of the atmosphere to those of the present, in which pressures of 180 lb. and 200 lb. to the inch are common, sometimes exceeded, and pressures of 60 lb. to 80 lb. low. There are certain early types, often illustrated, which are not made now, though their use lingers in some old firms. These are the externally-fired egg-ended boiler, the Rastrick, the box boilers, and the old type of haystack. Also the use of iron for boilers has been nearly discarded for that of steel, with all the practical advantages that result from the use of the latter. The superiority of mild steel over the boiler qualities of wrought iron is the reason why few boilers are made of iron now. Being highly ductile, severe work, such as bending and flanging, can be done upon steel that could not be done upon iron. Its elastic limit being high, it will stand more severe strain than iron without undergoing permanent set. Being of high tensile strength, higher pressures can be carried in steel boilers than in iron with equal scantlings, or equal pressures with lighter scantlings, or with larger diameters. Owing to the absence of lamination in steel plates, they are less liable than iron to deteriorate due to overheating. The methods of constructing boilers have been treated on page 3095. We shall therefore be able to confine the present remarks to the design of the principal types of boilers now made.

Classification. Cylindrical boilers may be classified in two great groups, *horizontal* and *vertical*, signifying that the longitudinal axis of the boiler is either set horizontally or vertically. The horizontal types include the Cornish, or one-flued, and the Lancashire, or two-flued; the modified Lancashire, with three or five flues; the Galloway, with the two flues united into one behind the bridge, therefore a breeches flue type, with a large number of conical tubes. In the horizontal group, all marine—Scotch type—boilers are included, and these also are classified variously. It also includes the multitubular arrangements as used on the locomotive and marine boiler types, which arrangements are also adopted in a good many Cornish and Lancashire boilers. The vertical group includes plain and multitubular forms in many and varied designs. Outside these lies the great group of water-tube boilers. In these, though tubular, the water is contained in nests of tubes around which the fire plays; while in the multitubular boilers proper the flame and hot gases pass through tubes in the water space. The distinction is a vital one, constituting entirely different types.

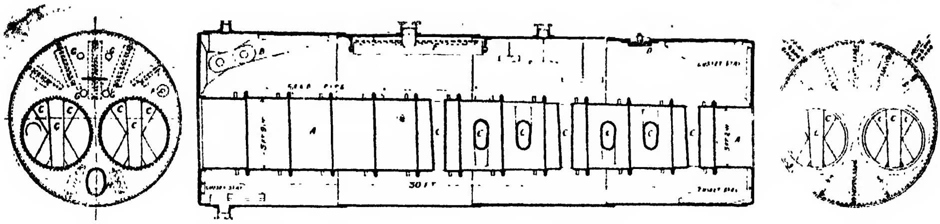


100. CROSS SECTION THROUGH CORNISH BOILER AND SETTING

Horizontal Boilers—The Cornish and Lancashire. The Cornish is a single-flued boiler, shown in cross section in **100**. The flue lies centrally in the horizontal direction, but below the centre in the perpendicular axis, in order to give ample water space above. In Continental types it is placed to one side. A considerable space is occupied by the flue: thus in a boiler 5 ft. in diameter, the flue is 2 ft. 7½ in. in diameter. This is a large space to take away from the water and steam space, and leaves little room between the bottom of the furnace flue and the bottom of the boiler shell, and renders cleaning difficult in the contracted spaces. The Lancashire [**101**] resembles the Cornish in all respects, except that it has two furnace flues instead of one, which is preferable, as boilers increase in size. The minimum diameter of the flues for Lancashire boilers is about 2 ft. 4 in.—2 ft. 9 in. is better—and they range thence to 3 ft. 6 in. The diameter of the flues controls the size of the shell for a given boiler. There should not be less space than 4 in. or 5 in. between the flues, or between the flues and the sides of the shell. Shells range from 6 ft. to 9 ft. in diameter. Lengths vary from about 14 ft. or 15 ft. to 30 ft., 28 ft. or 30 ft. being a usual standard length for a large Lancashire boiler. Roughly, the length of a Cornish or Lancashire boiler is equal to from three and a half to four times the diameter.

The illustration selected [**101**] is one of the standard 30 ft. by 9 ft. boilers by Tinkers, Ltd. It differs from ordinary types in the gradual reduction of the furnace flue, A, toward the back end, and in the hinged character of the gusset stays, B, over the furnace flue. The other gussets are of plated type. The conical tubes, C, are set as in the usual practice, vertically, and at angles of 30° to right and left; D is the manhole; E is the anti-priming pipe whence dry steam is taken. Only the front and back end plates are single-riveted [see the enlarged detail]. The end plates receive additional support from the furnace flues and the gusset stays. Elsewhere the circular seams are double-riveted. The longitudinals eams are treble-riveted through butt straps. Each ring is formed of a single plate, and they break joint in the manner indicated. Such a boiler would, in the old days, have required eighteen iron plates. The furnace flues are plain cylinders, with Adamson flanged seams [see page 3102, and Figure **226**] the seams hit and miss as shown.

The water circulation is sluggish in the bottom of Cornish and Lancashire boilers because the water there lies below the furnace flues. At one



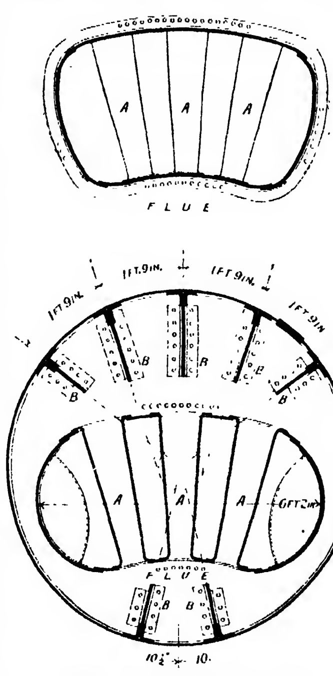
101. LANCASHIRE BOILER, 30 FT. BY 9 FT. (Tinkers, Ltd.)

time this was aggravated by the bad practice of bringing in the cold feed water there, which is now always brought in above them. The seating for the check feed valve which regulates the water supply is seen at F. The seatings for the water gauges are shown at G. H is the mudhole. The various seatings on the top are for different valves. J is for the high steam and low-water safety valve, K is for the junction valve, L for the deadweight safety valve, M is the seating for the blow-off cock.

Galloway Tubes. These, shown at C [101], are so termed from their inventor, and are also called *conical tubes*, from their form. They have added much to the efficiency of both Cornish and Lancashire boilers by improving the circulation between the dead water at the bottom and the hot water at the top. The conical form is imparted simply to permit of the insertion of the smaller end of the tube through the hole cut for the larger end. The tubes are arranged in different planes, vertically and diagonally, in order to allow the hot gases to strike fairly against each successive tube.

The Firegrate and Flues. The firegrate, shown in **103** and **104**, occupies the front of the flue in Cornish and Lancashire and horizontal boilers to a length of 5 ft., 6 ft., or 7 ft. Thence the products of combustion pass through the furnace flue or flues to the rear, and out at the back of the boiler [see the section **100**]. Thence they return through brickwork flues by what is termed a *split draught*; that is, the hot gases pass down the downtake at the rear, and back to the front of the boiler by a central flue of brickwork [**100**, A]. Thence they are diverted to right and left under the action of the chimney draught into side flues, B, B, and so out at the chimney [compare also with **103**]. Frequently an economiser, or feed water heater, is placed in the passage of the gases between the termination of the flues and the entrance to the chimney, so that they yield up heat to the boiler feed water contained in the heater pipes. The gases in their passage through the brickwork flues render up heat to the water in the lower part of the boiler, which is least affected by the heat from the furnace. The brickwork flues are therefore an essential feature of these *land* boilers, as they were formally termed. The boilers are supported on seatings of brickwork, [**100**], which form the walls of the flues. Dampers are provided to regulate the draught. The result is that the boilers are very economical, easy to operate, and have long been deservedly popular among mill and factory proprietors. The fire bridge [**103** and **104**] is a bridge built of brick at the rear end of the firegrate in all boilers of this group. It reaches to within from 9 in. to 12 in. of the top of its furnace flue, and its function is to delay the escape of the hot gases into the smoke flue, and so to promote complete combustion.

Three and Five Flued Boilers. Some of the largest boilers have three fire tubes—two below and one above, centrally. The object is to still further increase the advantage of the substitution of smaller for large flues. Boilers are also made with five flues for burning waste gases.

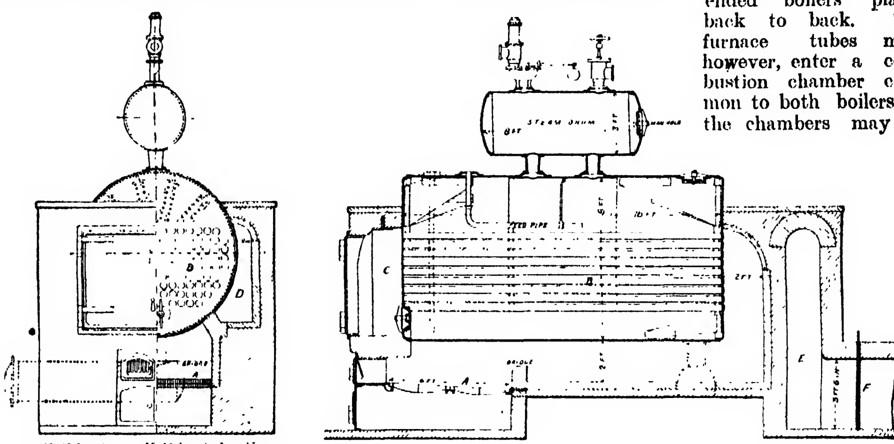


102. GALLOWAY BOILER
A. Conical tubes *B*. Gussets

The Galloway Boiler. This is a modification of the Lancashire type, which gives greater efficiency by increasing the number of conical tubes and providing a number of water pockets. The tubes are not placed as in the ordinary boiler, but in a *breeches* arrangement, in which the two furnace tubes unite in a single smoke flue beyond the bridge [shown in section in **102**], which flue contains the Galloway tubes. A modern full-sized boiler will contain thirty of these tubes, besides four side pockets, which help to break up the flame and heat the water.

Multitubular Boilers. There are considerable numbers of Cornish and Lancashire boilers made of the multitubular design. That is, the furnace flue terminates a little way beyond the bridge, and the hot gases pass through a nest of tubes to the back of the boiler. The tubes are larger than those of locomotives, being generally about from 3 in. to 4 in. in diameter. They vary in number from about 20 to 90. In some designs the tubular system is adopted entirely, as in **103**, which is a horizontal boiler

mounted exactly like a Cornish, over brickwork flues, but is externally fired. It is surmounted with a large steam drum. The flame and products of combustion pass from the grate A along under the boiler, back through the tubes B to the smoke box C at the front end, thence to right and left through the side flues D to the downtake E, and chimney. The damper F regulates the draught.



Half front elevation — Half front elevation, with brickwork removed

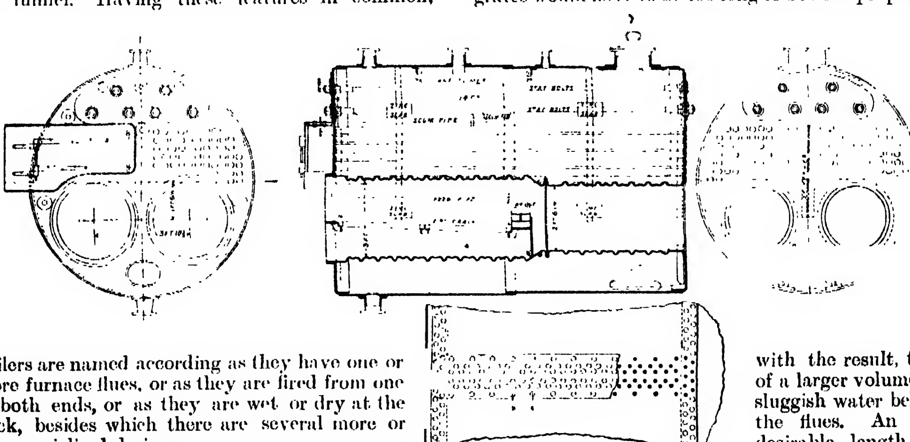
103. MULTITUBULAR BOILER (Tinkers, Ltd.)

Horizontal Boilers—Marine Type. These are commonly termed *Scotch* boilers, and they include several modifications. They are all of *return-tube* design. That is, the products of combustion on leaving the back of the furnace flue return through a nest of tubes which traverse the water space immediately above the furnace [**104**]. At the front of the boiler there is a large casing of sheet iron (not shown) into which the tubes enter. The smoke passes thence into the funnel. Having these features in common, boilers are named according as they have one or more furnace flues, or as they are fired from one or both ends, or as they are wet or dry at the back, besides which there are several more or less specialised designs.

Single-ended Boilers. These are so termed because they are fired from one end only. An example occurs on page 3099 [220 and 221]. The furnace flue C in that figure opens at the end opposite the grate D into the combustion chamber G, which is attached both to the flue and to the shell, and extends up into the latter high enough to cover the ends of the return tubes. Water entirely surrounds the chamber, excepting where it is connected to the furnace ... water covers the chamber and the tubes the depth of several inches, and the space above occupied by steam.

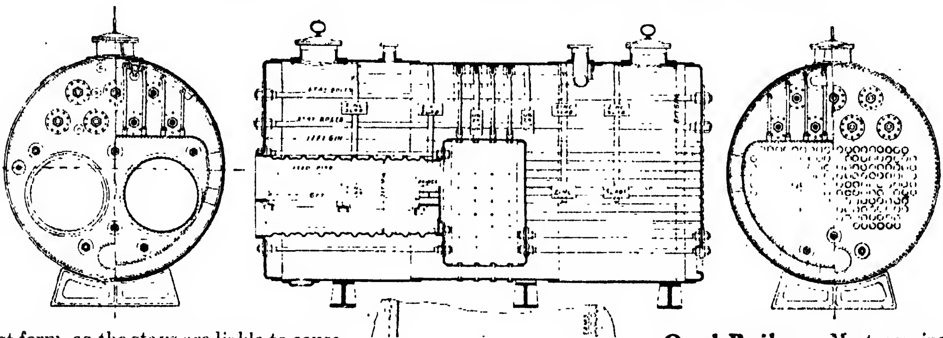
Double-ended Boilers. These are fired from opposite ends, and are essentially two single-ended boilers placed back to back. The furnace tubes may, however, enter a combustion chamber common to both boilers, or the chambers may be distinct, in which case the resemblance to two independent boilers is most pronounced.

Number of Furnaces. Only in the smaller boilers, or those up to about 8 ft. or 9 ft. in diameter, is a single furnace used, the diameter of which should not usually exceed 48 in., and is seldom less than about 36 in. Boilers of 9 ft. and over and up to 13 ft. 6 in. diameter should have two furnaces; up to 15 ft. three furnaces, and over that size, four. If the attempt were made to obtain evaporative power by lessening the number of furnaces and increasing their diameter, the grates would have to be too long to be fired properly, with the result, too, of a larger volume of sluggish water below the flues. An undesirable length of grate would be necessary to get the required grate area, which increases only as the diameter, while the cross section of the flues in which the products of combustion have to be utilised increases as the square of the diameter, which is a correspondingly greater ratio. The question of the number of furnaces involves also that of the combustion



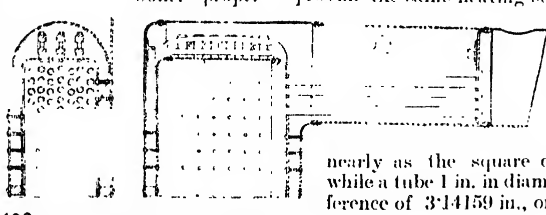
104. DRY-BACK MARINE BOILER (Tinkers, Ltd.)

chambers. The simplest and the worst design is that in which all the furnaces open into one common combustion chamber. The disadvantages are that a leaky tube places the whole boiler *hors de combat*, and that the firing of any furnace produces a rush of cold air all over the surfaces of the chamber. In another design all the furnaces at one end meet in a common combustion chamber and all those at the other end in a similar chamber, the two chambers being divided by a water space. This is not the best form, as the stays are liable to cause trouble. Another design is that in which each furnace has its own independent combustion chamber. It is satisfactory, except on the score of price and weight, and is not, therefore, used so much as the next one named. In this the furnaces, which are opposite to each other, have a common combustion chamber. Each chamber is divided from the one adjacent by water space. To lessen risk of leakage of the tubes, due to the inrush of cold air on the opening of one of the furnaces, a semi-partition, a kind of hanging-bridge of brickwork, is sometimes fitted across the combustion chamber at right angles to the direction of the tubes, and coming some way down into it. This type of boiler is, perhaps, that most commonly used in marine service.



105 TWO-FLUED MULTI TUBULAR BOILER

Dry-back Boilers. The foregoing are all wet-back boilers—that is, the combustion chamber is backed by a water space, and this is the design which is almost invariably adopted. There is, however, a type—the dry-back boiler proper—in which the terminates with the furnace end and tube ends, the combustion chamber being formed with brickwork. Its principal advantage is cheapness. Figure **104** is a dry-back boiler by Tinkers, Ltd., the brickwork not being illustrated. The furnace flue goes right from end to end. There are 114 tubes, 3 in. in diameter, solid drawn. Twenty-four of these are *stay tubes*—that is, they are screwed and nutted at the ends to grip both inside and outside the end plates. There are no gusset stays required at the top, but only those at the bottom.



106. MULTITUBULAR BOILER OF ROAD ROLLER

(Aveling & Porter, Ltd.)

Composite Boiler. In another design of dry-back marine boiler, the combustion chamber is situated at the end of the firegrate just beyond the bridge, and the tubes are carried beyond the chamber instead of returning over the furnace, thus requiring a longer boiler than the usual design. The tubes enter the smoke-box at the farther end. Of the 3 in. tubes in this boiler, 183 in number, 40 are stay tubes. As the roof of the combustion chamber is flat, it is stayed to the top of the shell with *sling stays*, an alternative to the *bridge* or *girder stays* on page 3099 [220 and 221].

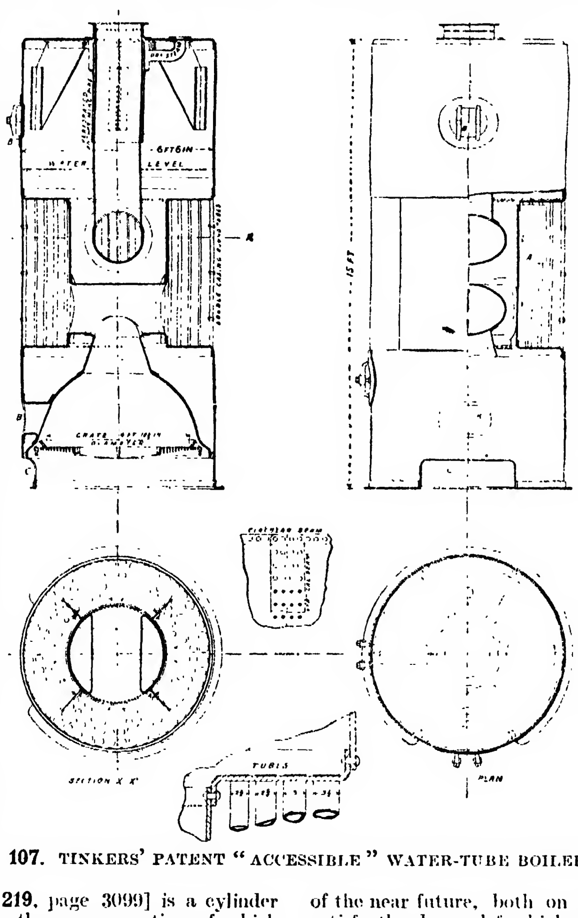
Oval Boilers. Most marine boilers are of cylindrical shape. But a number are made of the so-called oval form, which is, however, composed of two semi-circles connected by flat sides. The only advantage of this is that such boilers can be set in spaces where width is contracted.

The Locomotive Type. In this, the distinguishing feature is the large number of smoke tubes which, passing through the water, assist in the rapid generation of steam. For remarks on these, see the article on Locomotives, page 6514; see also **227**, on page 3101. This type of boiler is used extensively in other ways. It is employed on torpedo boats, differing chiefly in the fact that the firebox is wider, and generally longer. It is used for portable and traction engines, **106**, and for the under-type engines.

In order to obtain a large amount of heating surface from tubes, they are made relatively small, and closely packed. A few large tubes would not provide the same heating surface as a large number of small ones, because while the circumference of a tube increases only as 3·14159 of its diameter, the space occupied increases nearly as the square of its diameter. Thus, while a tube 1 in. in diameter will have a circumference of 3·14159 in., one of 6 in. diameter will have a circumference of $6 \times 3{\cdot}14159 = 18{\cdot}84954$ in. But it will occupy an area of cross section of 28·1744 in. So that in an inch tube, the ratio of circumference to cross section will be 3·14159 to 0·7854, and in a 6-in. tube it will be 18·84954 in. to 28·1744 in. Therefore, by placing a large number of small tubes in a boiler, a much greater heating surface is obtained than by the insertion of a few large ones in the same space. But this must not be carried too far, for then the tubes and spaces are liable to become choked and the circulation impeded.

The Vertical Boilers. The horizontal-flued boilers have a good reputation for staying

capacity. That is, they will maintain a large supply of steam with little fluctuation. The volume of water and steam space is large, the firing can be done very regularly, the water level and the steam pressure can be maintained very easily. On the other hand, they are not suitable for any but permanent service, being necessarily located in one spot over brickwork flues, and being moreover very massive. Hence, for a large extent of service the vertical boiler is employed. It is never made in dimensions so large as those of Lancashire boilers, though the largest vertical are as big as many Cornish boilers. They require no brickwork, and no foundation, and can, therefore, be easily transported and set down anywhere. But they are generally used as a fixed element, as on the foot plate of a steam crane, or a hoisting engine, or a fire engine. Immense numbers are used, more because of their great convenience than for high efficiency. They are not so economical as the Cornish and Lancashire, the steam supply runs down very rapidly under severe service, because the steam and water areas are small, and firing cannot be done so well as in the other boilers named, because the grate is not suitable for preliminary coking of the fuel, being of rather small dimensions, and having no dead plate. Still, for intermittent kinds of service they are useful and popular, and steam can be got up in them in a small fraction of the time required in the boilers laid on brickwork flues.



107. TINKERS' PATENT "ACCESSIBLE" WATER-TUBE BOILER

The vertical boiler [see **218** and **219**, page 3099] is a cylinder standing on its base, the upper portion of which is occupied by steam, and the lower by water, covering and surrounding the internal furnace (firebox). This also is cylindrical, but is a frustum of a cone, the amount of coning on the depth of the firebox amounting to about 3 in. in the diameter. The reason of this is to facilitate the disengagement of the bubbles of steam as they are formed in the narrow annulus between the outer shell and the inner firebox. The two are united by means of a ring at the base—the foundation ring—or by flanging, and also by a ring encircling the firehole. In large boilers a few screwed stays also connect the two. The crown of the firebox is connected to the crown of the shell by means of an uptake, through which the smoke and products of combustion pass into the chimney. In the larger boilers screwed stays also connect both crowns. All boilers of this type, except the smallest, are fitted with cross tubes, ranging from one to three. These are set at angles with each other, and are often inclined slightly from the horizontal to lessen chance of deposit occurring. Mudholes are set opposite the tubes.

Generally the designs of tubular vertical boilers involve firetubes. There are many of these, varied in all conceivable fashions. Many are objectionable, because of the difficulty of cleaning and repairs. A novel design is that in **107**, in which water tubes are fitted, the flame surrounding them being distributed and broken up by the two cross tubes, assisted by the four *diffusion plates* [A] seen in plan and elevation. The circles of tubes increase in size towards the circumference where the heat diminishes. Eight of the outer circle are stay tubes. B is the firing hole, and C the ashpan opening. The drawing is largely self-explanatory.

Water-tube Boilers. These have been slowly winning their way to favour as rivals to the Scotch boiler for marine service, and to the Cornish and Lancashire for land power plant. They are used largely in central stations, and are as popular in America as in Europe. They are economical, and the furnaces can easily be designed for burning inferior fuel. Water-tube boilers are the type of the near future, both on land and sea. They satisfy the demand for high pressures with diminution in weight. This is chiefly due to the difference in confining water and steam in the body of a Scotch marine boiler, which is a casing of large diameter, measuring from 14 ft. to 16 ft., and confining it in many tubes of small diameter. The steel plates of which a large marine boiler are made range from $1\frac{1}{4}$ in. to $1\frac{1}{2}$ in. in thickness, and this thickness is necessary to withstand steam pressures of from 150 lb. to 200 lb. to the square inch. But small tubes only $\frac{1}{4}$ in. thick will endure pressures of 300 lb. or 400 lb. to the inch with absolute safety. A boiler, therefore, having water-tubes of 3 in. in diameter, and but $\frac{1}{4}$ in. thick.

is stronger than a cylindrical boiler the shell of which is 1¼ in. thick.

The Belleville boiler is the pioneer broad type on which many others have been designed, the main characteristic of which is the fact that the tubes are inclined within a few degrees of the horizontal. The methods by which they are made to communicate with the steam drum vary in different designs, and their method of fitting also. Some of these differences are of much practical importance; but the only point which we note here is that these boilers constitute a class by themselves, and that their value lies in their capacity for regular service, which renders them suitable for battleships and cruisers, as well as for the mercantile marine, in which they are largely used, and for land service. The boilers of this broad type include the Belleville, the Niclausse, the Babcock and Wilcox, the Dürr, and the Lagrafel d'Allest. The other main type of boiler is that which is used chiefly for torpedo-boats and destroyers. The best known examples are the Yarrow and Thornycroft, the Normand and the Du Temple Guyot. There the tubes are arranged in groups far removed from the horizontal position, being, in fact, sloped several degrees away from the vertical, which imparts to their casings an approximately triangular outline instead of the square, box-like form of the casing of the other types. This broad difference is most important. The nearly vertical slope of the tubes permits the steam to escape more rapidly into the collector or drum than the nearly horizontal arrangement does. Hence these boilers are very rapid steam raisers, and are thus admirably suited for torpedo-boat service. These boilers represent the very highest developments of the water-tube types. They are the nerves and sinews of the torpedo-boat and kindred craft. But the type which is best suited for this service is not the best for a battleship or on land. Not only in naval service, but also in the mercantile marine, these boilers are displacing the older types. Water-tube boilers predominate on the Continent over all other kinds, but they are not as yet great favourites in Great Britain, the exceptions here occurring chiefly in some of the modern works for producing electric light and power.

The Babcock and Wilcox. We can illustrate only one type here [108]. It is one of the few very successful kinds. From five to six millions of horse-power of these boilers are in use in various parts of the world. One of the land type is shown in the figures, encased in brickwork. From the firegrate A the heat passes up among and along the inclined tubes B. C is the drum which contains water and steam. The circulation is set up in the water by the heat, the steam generated in the water-tubes B is liberated, and rises to the upper part of the drum, and water from the lower part of the drum comes down to occupy its place. This circulation goes on through the headers D, D, which are steel boxes into which the ends of the tubes are secured by expanding. The brickwork is enclosed in a casing of sheet steel, and doors are provided to the furnace and to the ends of the tubes. The various valves, gauges, and damper will be noticed.

Combustion. The economical results of combustion are so different under different conditions that it will be well to state what goes on in a boiler. In the most perfect combustion that can occur, the air supplied would be in the exact quantity requisite for the complete combustion of the carbon and hydrogen in the fuel, without leaving any surplus. A portion of the oxygen in the air would combine with the hydrogen liberated from the fuel to form water, gas, or steam, the remaining portion uniting with the gaseous and solid incandescent carbon to form carbonic acid. The steam, the carbonic acid gas, and the inert but heated nitrogen, dissociated from the oxygen of the air, pass on into the chimney, having their heat abstracted from them during their transit. This is a result achieved in few, if, indeed, any furnaces, unless perhaps for exceptionally short periods. The perfect diffusion and intermingling and chemical union of the elements in their combining weights results in intense heat, the heat due to chemical energy; while having no elements left unsatisfied, there is no waste and no thick smoke, the waste gases being nearly colourless. The more nearly practice can be made to approximate to this perfect combustion the better.

NATURAL PRODUCTS

Following BACTERIOLOGY from page 6784

WORLD'S COMMERCIAL PRODUCTS

The Chief Commercial Natural Products of the World not Described Elsewhere in the "Self-Educator"

A large proportion of the natural products of commercial value have been dealt with in the SELF-EDUCATOR in the places in which they fall naturally, under the particular industry or manufacture in which they are used. But there remain many which must escape treatment on these lines or which are not themselves described as fully as their importance merits. An endeavour has been made to cover these deficiencies in the following pages. The information given in the previous pages will be found by consulting the names of specific articles in the General Index, beginning on page 6900

ABACA—See *Manilla hemp.*

Acacia—The acacia is a genus of thorny trees of which there are several hundreds of varieties. They flourish especially in Africa and Australia. There are several acacias that yield commercial products. The babul tree of India is the *Acacia arabica*, and its wood is a useful timber; its leaves are used as fodder, its bark is of value in tanning and in dyeing, and its gum is used as a substitute for gum arabic. The *Acacia senegal* of West Africa and India yields *Gum senegal* [see *Gums*]. *Acacia catechu* is the source of extract of catechu, which is prepared by boiling the wood chips in water and evaporating the decoction until the extract thickens. The dose of this extract, which is official in India and other colonies, is 5 grammes to 20 grammes; it is given as a tonic astringent in diarrhœa and intestinal hemorrhage. The catechu of the British Pharmacopœia is from another source, the *Uncaria gambier*.

Aconite—Aconite or monkshood [see also pages 352 and 731] is a poisonous plant (*Aconitum napellus*), and the root is now the only portion used, its sole employment being medicinal. It grows in England and in the mountainous regions of Central and Southern Europe. It is collected in autumn, after the leaves and stem have fallen. The roots are trimmed, washed, and dried. The active principle is *aconitine*, which, as an internal remedy (official dose, two grains), is used as a febrifuge and to relieve pain, and as an external remedy for the relief of pain. Aconite poisoning has been successfully treated by hypodermic injections of digitalis.

Alder—The alder (*Alnus glutinosa*) grows in Europe, North Africa, and the North of Asia. A humid soil is favourable to its growth. [For its botanical classification see page 355, and for its physical properties see pages 1260 and 1261.] In appearance the wood is of a reddish-yellow colour, and resembles birch, to which it is akin. It stands immersion in water well, for which reason it is used for pile work, but it decays when wet and dry in frequent succession.

Allspice—*see Pimento.*

Almonds—Almonds are the fruit of the tree *Amygdalus communis*, which grows in the countries bordering the Mediterranean, and in certain parts of Asia. There are two varieties of tree, one yielding sweet almonds and the other yielding bitter almonds. The best almonds are those from Malaga and known as "Jordan" almonds. They have nothing to do with the river of Palestine, and the name may be a corruption of the French word *jardin*, garden. Other varieties imported into this country are known as Valentia, Sicily, and Barbary, all being sweet almonds, used as a dessert fruit and in the manufacture of confectionery. There are also several varieties of bitter almonds—French, Sicily, Barbary, etc.—and from these essential oil is expressed. The bitter almond yields both an essential oil and a fixed or fatty oil; the sweet almond yields only a fixed oil. The best oil is obtained from Majorca almonds. Bitter almonds are generally used, as the cake that is left may be used by perfumers. The residue from the oil-press is steeped in salt water for a day, and the oil is distilled off. The crude oil is suitable for perfumers' use, but if it is to be used for medicinal purposes, the prussic acid contained must be removed. An artificial oil of bitter almonds, otherwise known as *essence of mirbane*, is made from coal tar [see page 4971].

Aloes—Aloes is the dried juice of the leaves of certain trees growing in Africa and in the West Indies. The best variety is Barbados or Curaçao aloes (*Aloe vera* and *Aloe chinensis*), and others are Socotrine or Zanzibar aloes (*Aloe perryi*), and Cape aloes and Natal aloes, the last two of which are not regarded as official by the British Pharmacopœia. The juice is evaporated by boiling to a solid mass or extract, in which condition it reaches our market. Medicinally, aloes is used as a purgative (dose, 2 gr. to 5 gr.), and is reputed to be the chief ingredient in many of the most popular patent medicines. It is prepared as pills, tinctures, mixtures, and other preparations. Its active principle is *aloin* (dose, ¼ gr. as an aperient and 1 gr. as a purgative).

Alum—Alum [see also page 1721, 4780, 5993] is found native as an incrustation upon rocks in volcanic regions, but the greater part of the alum of commerce is obtained from alum shale, a bituminous shale found in this country, in Norway and elsewhere. Rock alum, as the native alum is called, is found in the district around Naples, and in Hungary. It consists chiefly of sulphate of alumina and silica. It is reduced by roasting in kilns, and afterwards by being kept moist for some months, after which the alum is dissolved out and re-crystallised. Alum is used extensively in textile dyeing and printing [see page 5779], in sugar refining, in papermaking, in photography, and for many other industrial purposes. In medicine alum is used as an astringent.

Amber—Amber is a fossil resin, the chief source of which is the Baltic sea, from the bed of which it is detached and washed up. It is used chiefly for the mouthpieces of pipes and cigar-holders, for beads, and, dissolved in alcohol, it is made into varnish. The chips of amber are fused under pressure, making an artificial amber, which is stronger than the natural resin. It is also made artificially from copal, camphor, and turpentine.

Ambergris—Ambergris is a substance of waxy texture and consistency, streaked or veined, and of light grey colour, found floating in the sea. It is supposed to be a biliary secretion of the spermaceti whale. It is found in masses usually of only a few ounces, yet occasionally running up to 2 cwt. It has a pleasant odour and is used extensively in perfumery, not so much, however, for its own perfume, but because it makes other perfumes less fleeting than they would otherwise be. It is readily soluble in oils, and in ether and absolute alcohol. It owes its properties to the aromatic substance *ambreine*. Its market value is about £5 per ounce.

Aniseed—Aniseed is the seed of an annual plant (*Pimpinella anisum*), that grows in France, Spain and the Levant. *Star anise* is the seed of *Illicium anisatum*, a Chinese plant; it resembles European aniseed very closely. The two varieties are equally valuable, being almost indistinguishable in flavour, and both yield an oil by distillation. Aniseed is used as a flavouring ingredient in pastry and in liqueurs, and the oil is used medicinally (dose ½ minim to 3 minims), as a stimulant and carminative.

Annatto—Annatto is a dye in the form of a paste, which settles after macerating with water the pulp and seeds of *Bixa orellana*, a plant that is extensively cultivated in the French colonies in South America. It is used in dyeing [page 5907] and as a colouring for butter and cheese.

Apricot—The apricot (*Prunus armeniaca*) is a species of plum, supposed to have been native to Armenia. It is grown in all parts of Europe except the North, in Syria, Egypt, Eastern Asia, and America. In England the apricot is usually grafted on the plum, but the chief supplies for our market come from France. There are many varieties of apricots, and the *mush-mush* of the Levant is dried and compressed apricots.

Arachis—*see Ground-nut.*

Archil—When subjected to the action of ammonia and air, certain lichens of Ceylon and Portuguese East Africa yield the violet-blue dye known as *archil*. The dye is used for wool and silk. Archil is a liquid dye which, on evaporation, gives *cudbear*, and if further treated with ammonia and lime makes *litmus*, familiar to chemists as the agent for determining acids and alkalis.

Areca—Areca nuts, or betel nuts, are the seeds of *Areca catechu*, an Indian palm which grows also in Ceylon and the Malay Peninsula. The nuts are mottled brown and white in appearance, and are about one inch long. The natives chew the nuts, first cutting them into thin slices, adding lime, and wrapping in betel-pepper leaves. The habit has as strong a hold as has the opium habit upon the Chinese, but apparently has no evil effects. Areca nuts are

used in Western countries as a medicine for dogs and as an ingredient in dentifrice. Cutch, used in dyeing, is made from areca [see page 5906].

Arrowroot—Arrowroot is obtained from the underground stems of a tropical plant, *Maranta arundinacea* [for botanical classification see page 355]. The finest arrowroot comes from Bermuda. The root stems are white in colour, and grow up to 2 ft. long. The starch which they contain is extracted by macerating and washing them, allowing the fibrous outside portion to be removed, and the milky liquid remaining to settle, after which the sediment is taken out and dried. Arrowroot is rich in starch, and is an easily digested food, hence its value for invalids, but it is low in nutritive value. It is extensively adulterated with potato starch. East Indian arrowroot is obtained from different varieties of *Curcuma*, a plant of the ginger family. Florida starch or Florida arrowroot is made from species of *Zamia*.

Ash—There are several scores of varieties of ash-trees. English ash (*Fraxinus excelsior*) provides the most valuable timber [for its physical strength see pages 1260 and 1261; for botanical classification see page 354, and for principal uses see General Index].

Aspen—See *Poplar*.

BAMBOO—The bamboo (*Bambusa arundinacea*) is the name applied to a group of grasses with woody stems that grow in tropical countries, notably India, China, Japan, and to a smaller extent in Africa and America. The common bamboo (*Bambusa vulgaris*) sometimes grows to a height of over 100 ft., with a base diameter of 1 ft. It flowers at intervals of some years, and the grain is used as a food in India. In the West Indies the young shoots are eaten. The hollow canes are solid at the nodes, and this makes them easily cut into vessels. They also serve as pipes and as curtain poles. Cheap tables and other furniture are made from bamboo, and bicycle frames were made from them a few years ago, but this was a fad which speedily expired. There are over 200 different species of bamboo, and several of them are hardy enough to be grown in English gardens. The young shoots of bamboo are used as a paper-making material, the older stems being useless on account of the silicious external coating which they have developed. [See also page 5724.]

Banana—During recent years the banana has advanced in favour in Great Britain until it ranks high among our imported fruits. Our chief source of supply is Jamaica and other West Indian islands. The cultivated banana is seedless, and is propagated by cuttings. The true banana is the *Musa sapientum*, the *plantain* or *pisang* being a subvariety. The Jamaica banana-tree is about 12 ft. in height, and is larger than the Canary or China banana, which grows about 6 ft. high. The plant has root stems which send forth leaves, the petioles of these leaves forming a hollow stem. The blades spread out from the leaf sheaths, and are 6 ft. long or more. The fruit-carrying stems, which spring straight from the roots, emerge from among the leaves. The fruit grows in huge clusters, such as may be seen in our fruit markets—a cluster weighing up to half a hundredweight. The fruit is gathered green, and ripens on its way to our market. The banana is an important article of food in the countries where it grows, but is generally despised by the higher classes. In Jamaica it is given to cattle. The dried flour of ripe bananas is made into bread and cakes, and has some nutritive value, containing about 20 per cent. of sugar and 5 per cent. of albumin, the remainder being nearly all water.

Basswood—See *Lime*.

Baywood—See *Mahogany*.

Bebeeru—See *Greenheart*.

Belladonna—The belladonna, or *Deadly nightshade* (*Atropa belladonna*) is a perennial poisonous plant that grows in Europe, Asia, and America. The root, the stems, and the leaves are used in medicine, being of value for the active principle *atropine*, which is isolated by distillation with alcohol and chloroform. The dose of the leaves is 1 gr. and of the root ½ gr. (official U.S.A.), but in this country the drug is administered only when prepared as an extract or tincture, or as a preparation of atropine, while externally it is used as a liniment, an ointment and a plaster. Externally, belladonna is applied for rheumatism, neuralgia and local inflammations. Internally it is given for spasms, heart failure, fever, acute sore throats, etc., and in the form of atropine is applied to the eye. The antidotes to belladonna poisoning are the stomach-pump and emetics, followed by stimulants, also apomorphine and pilocarpine injected hypodermically.

Benzoin—Benzoin, otherwise called *gum benzoin* or *gum Benjamin*, is a resinous balsam from the *styrax benzoin* of Java and Sumatra. The chief uses of benzoin are in the manufacture of perfumery; as an incense for church use; and in medicine. When lard is used as an ointment base, benzoin is usually added to preserve it sweet. As an external application benzoin is stimulating and antiseptic; compound tincture of benzoin, which is known as *Friar's balsam*, is in esteem as a dressing for wounds. Internally, benzoin is antiseptic, and a stimulating expectorant.

Betel Nut—See *Areca*.

Bibiri—See *Greenheart*.

Birch—The common birch (*Betula alba*) is the most graceful tree of our woods, and is one of the hardest. It can grow in the most exposed situations, and is the only tree found in Greenland. It flourishes throughout Northern Europe and Asia. It grows as high as 80 ft., and has small, serrated leaves, and its fruit is a small nut. The thin outer skin of the bark, which has caused it to be known in some districts as the *silver* birch, was formerly used as a writing material. The bark has been used extensively for canoes by the North American Indians, and in Lapland it is used as a roofing material—two evidences of its enduring qualities. It contains about 10 per cent. of tannin, and is used in leather manufacturing—both in this country and in Russia. Russia leather owes its characteristic properties to birch bark, which, in addition to its tannin, contains an aromatic oil which the leather absorbs. The oil is extracted from the bark and used in leather dressing, and also as an antiseptic for open wounds by Russians. Birch trees are easily propagated from seeds, which are sown in spring in a fine sandy soil, which should just cover them. The wood is soft but durable, with a close and even grain. It is largely used for chair and furniture manufacture, and much turned woodwork is made from it. Selected pieces with fine wavy markings on the surface are used in the form of veneer. There are numerous varieties of birch in Europe and America.

Black currants—See *Currants*.

Bog oak—See *Oak*.

Borax—Borax is biborate of soda and occurs naturally in several parts of the earth, although it is also manufactured from boracic acid obtained by evaporating the waters of the volcanic lagoons of Tuscany, and from borate of lime found in Peru. The oldest source of native borax is Tibet, and it is imported by way of India. It comes from the East under the name of *tincal*, and is frequently received refined, the operation of refining being performed by dissolving it in water and allowing it to recrystallise. The chief source of borax is now the Pacific slope of North America—the Columbus Valley in the State of Nevada, the largest known borax field (10 miles long and 7 miles broad), being a desolate and forbidding region, devoid of vegetation except small saline plants. The most important use of borax is as a flux in glazing pottery and in welding and brazing metals. Boracic acid, the valuable antiseptic and antiputrefactive, is obtained by the action of sulphuric acid on borax. It is used as a powder, as an ointment, a lotion, and in many other forms. Both borax and boracic acid are used to preserve milk and other foods; medical opinion is divided upon the value of this practice, many experts holding that, especially in the case of children, it is pernicious.

Boxwood—Common boxwood (*Buxus sempervirens*) is an evergreen shrub familiar as an edging for garden plots. It is propagated by cuttings, and is developed best by division. It grows slowly. Some varieties of boxwood may reach the height of 20 ft. The wood is hard and close, fine grained, and of even texture. It is most familiar as the material from which carpenter's rules are made, and it is also used for wood engraving and tool handles. Owing to the small supply of true boxwood, a substitute has been found in the West Indies, and is largely used. It is known as West Indian boxwood, or white cedar.

Brazil Nut—The Brazil nut that reaches our market is the fruit of a tree (*Bertholletia excela*) that grows in Brazil, Venezuela, and Guiana. The nuts or seeds—usually from 18 to 24 in number—are contained in a hard shell of round shape and about 6 in. diameter. This outer shell is broken, and the seeds are extracted and dried in the sun before being packed for export. The nuts are rich in oil, of which they can be made to yield 60 per cent. of their weight. The process of oil extraction consists in roasting the nuts and expressing the oil by pounding and pressing. The oil may be recovered also from the unroasted nuts. When fresh, Brazil nut oil, or *Castanha oil* as it is usually termed, may be used for culinary purposes; but as it soon turns rancid its use is chiefly for soap-making and burning.

Broom corn—The broom corn is extensively cultivated for the fruiting stalks, which are cleared of seed and used for carpet brushes or *carpet whisks*, as they are termed, and dandy brushes for stable use [see page 6106]. The plant is the grass *Sorghum dura*, which is allied to the sugar sorghum [see page 4354]. In America, broom corn is an important crop. It is sown as early as

possible in rows about 3½ ft. apart. When the shoots appear, they are hoed and soon afterwards thinned. Then a shallow cutting plough is run between the rows. The corn tops are cut while the corn is yet green, and the seeds are removed by a machine. Then the "brushes," or panicles, are spread on racks to dry and are packed for transport or go into the factory to be made into brushes. The corn stalks after the removal of the crops are 5 ft. to 6 ft. high; they are allowed to remain and are ploughed in the following spring.

Buckwheat—See *Millet*.

CAMEL HAIR—Camel hair is an important article of export from North Africa, Asia Minor, and Central Asia. It is the hair both of the dromedary or single-humped camel and of the two-humped camel proper. It has different degrees of fineness, and different colours according to locality, and to the age and individuality of the animal from which it is taken. One animal yields hair to the extent of about 10 lb. annually, the underside of the neck, the humps, and the upper legs being the places yielding hair sufficiently long to be commercially valuable. The hair from the younger animals is the finer. The Arabs weave it into cloth, making shawls, carpets, etc., with it. Some very fine cloths, which are both warm and soft, are made with it, and the modern prophet who followed the example of his ancient prototype in affecting "garments of camel's hair" would not necessarily lead a life of bodily discomfort. The so-called camel-hair brushes are made with the hair of squirrels' tails, and not with the hair of the camel.

Camphor — Camphor may be regarded as a resin as it is soluble in alcohol to the extent of 1 in 1¼, while it is soluble in water only to the extent of 1 in 700. It is a white crystalline substance obtained from the *Cinnamomum camphora* of Formosa and Japan. It reaches this country in the form of cubes of various sizes and of bells. Flowers of camphor is the powdered form. Camphor is used in wardrobes and museums to prevent the ravages of moths; as an ingredient in varnishes; in the manufacture of fireworks; and in medicine. For external application camphor is of value in sprains, rheumatism, and inflammation, and internally (dose 2 to 5 grammes) it is sedative, carminative, and antiseptic; and is given for nasal catarrh. It is also used extensively in the manufacture of celluloid or xylonite [see page 5470].

Carrageen—See *Irish Moss*.

Catechu—See *Areca* and *Acacia*.

Catgut — Catgut may be included among the natural products. It is made from intestines, but never from those of the cat, hence the name is entirely inappropriate. The intestines used are generally those of the sheep, and sometimes those of the horse, mule, and ass. The first process in manufacture is to clean the intestines thoroughly, after which the small ends are tied together and laid over the edge of the vat or tub, in which the greater portion of the intestine remains to soak for a few days, the water being frequently renewed. This treatment loosens the membranes. Now the intestines are laid on a sloping table and scraped with a steel instrument, which removes the external membrane, which is used for making the strings of tennis rackets and other purposes. The intestines from which the outer membrane has been removed are then steeped for one day and again scraped. The large ends are now cut away and sold for sausage skins. The small parts are again allowed to lie in water, and are then steeped in a bath of water in which potash and carbonate of potash have been dissolved (1 oz. of each to the gallon of water). Then they are drawn by hand or machine through a perforated thimble, which makes them uniform and smooth. After a final washing they are sorted according to size, and are ready for the market if to be sold unspun. If desired to twist them into cords, the lengths are sewn together, the external membrane removed at the first scraping being used as a thread. The sewn lengths are put in suitable numbers into a sort of rope-spinning machine, where they are twisted. They then go into a lead-lined chamber, where they are exposed to sulphur fumes, and are then dyed, smoothed, heated for a short time to make them firm, twisted into strands, and are ready for the market. The chief use of catgut is for musical instrument strings and for cords for clock-weights. It is also used as a cord for sash-weights in sliding window frames. The *silkworm gut* used for anglers' hooks is made by taking the silk glands from the body of the silkworm before it has begun to spin, by extracting therefrom the silk which is still glutinous, and by drawing it out into a thread.

Cedar—The cedars of Lebanon (*Cedrus libani*) are famous historically, and furnished the wood for the Temple of Solomon, but they have ceased to furnish timber for industrial use. The word cedar is now applied to the timbers of different trees which all have the qualities of yielding wood of even grain, light and soft and sometimes aromatic. Cedar used for lead pencils is chiefly the wood of *Juniperis bermudiana*, a red-coloured fragrant wood with the required properties. Red cedars of India and the West Indies are extensively used for cigar boxes. The Indian cedar, or *deodar* (*Cedrus deodara*), is looked upon as sacred, and is found around Indian temples. It is also used for sacred images, for coffins, and for railway sleepers. It is the chief tree of the Himalayas, and grows in forests. The different varieties of cedars are used for furniture—being valuable for the interiors of wardrobes, etc., on account of their immunity from attack by insects—and for wainscotting and turning. The consumption is so great that the market is always on the look-out for new sources or for woods with equally suitable properties. The cedar is one of the most imposing trees in an English landscape, its dense branches of dark leaves making it distinctive. Californian redwood (*Sequoia sempervirens*) is a red cedar, and its timber is the softest used in commerce. The mammoth tree of California (*Sequoia gigantea*) is another variety. It is found only in California, and specimens have been known over 400 ft. high and 110 ft. in circumference. One tree has had a tunnel made through its base, and a roadway goes through it. The *White Cedar* of the West Indies is used as a substitute for boxwood [see *Boxwood*].

Century plant—See *Sisal*.

Charcoal — Charcoal may be wood charcoal or animal charcoal, made by burning wood and bones respectively. In making charcoal intended for fuel, the usual practice is to pile the wood into heaps, usually in a dome-shaped kiln, and burn it until it is charred, the charred wood, which retains its original shape, being the charcoal. For the manufacture of charcoal for gunpowder special care is exercised in selecting the wood, which must be sound and free from adhering bark, and the heat is applied to the outside of cast-iron retorts in which the wood has been placed. Animal charcoal or *bone-black*, as it is also called, is made by heating bones in a retort or crucible, when gases are given off, some of which condense as a heavy oil, called *bone oil*. The chief uses of wood charcoal are as fuel in the manufacture of gunpowder, and as a non-conducting material for cold storage chambers. The chief use of bone charcoal is for decolorising syrups and in sugar manufacture. [See also page 4151.]

Cherry—The cherry is a small fruit of the plum family. There are many varieties of cultivated cherries, which have probably all evolved from *Prunus avium* and *Prunus cerasus*. Cherries are grown extensively in this country, although we derive some supplies from continental Europe and from Canada. Cherry trees should be planted in an open situation with a southern aspect. Standard cherry trees should be planted 24 ft. apart and bush cherry trees 6 ft. apart. Branches should be thinned in July and December every year. The late morello cherry, one of the best cooking varieties, grows best on a wall. Cherry brandy and various liqueurs, including maraschino, kirschwasser, and ratafia, are made with cherries. To make cherry brandy, fill a bottle half full of morello cherries —having cut off the stalks, wiped the fruit and pricked it with a needle. To each pound of cherries add twelve scraped bitter almonds and 3 oz. of sugar candy; then fill the bottle with brandy and allow the whole to stand for not less than six months, after which the liquor may be strained off. There are numerous varieties of cherries, the chief of which are the late morello and the Kentish (both good cooking cherries), the early yellow Elton, the May Queen, the Archduke, and the Black Eagle.

Chestnut—The chestnut (*Castanea vulgaris*) is found in Europe, Asia Minor, and in temperate America. It is also known as the *Spanish* or *sweet chestnut*. The chestnut tree is hardy, but the fruit comes to ripeness only if the situation is sheltered. The tree must have not less than 20 ft. of space all round. The wood resembles oak in colour, being of various shades of brown, and is used for similar purposes. The roof of Westminster Hall is alleged to be chestnut. The wood of old trees is somewhat brittle, and when strength is wanted, younger trees are selected. The nut of the chestnut tree is edible, and is usually roasted. When the nuts are ripe and fall, they should be gathered, taken from their husks and dried. The dried nuts are sometimes ground into flour, and made into bread or fritters. The Italians favour chestnuts as a food, and have several methods of cooking them. They make a porridge of chestnut flour, and call it *polenta*. They also sprinkle rose-water and grated cheese upon chestnut flour fritters, afterwards frying them in fresh butter. The chestnut is not particularly nutritious as a food, but roasting makes it much more easily digested. The nut of the horse chestnut (*Æsculus hippocastanum*) is too bitter for human food, but is sometimes given to cattle. It also contains an oil of a dark green colour, which is expressed,

and in Continental countries is regarded as a specific for rheumatism and gout.

China Grass—See *Ramie*.

Citron—See *Lemon*.

Clingstone—See *Peach*.

Coca Leaves—Coca leaves, the source of the valuable local anæsthetic *cocaine*, are the leaves of *Erythroxylum coca*, a shrub that grows in Bolivia, Peru, and in some parts of Southern Asia. The Bolivian leaves are brownish green in colour, oval, and vary in size from 1½ in. to 3 in. long, by from 1 in. to 1½ in. broad, with a characteristic odour and a bitter taste. Peruvian coca leaves are smaller and more fragile. Coca has remarkable sustaining properties upon both the mental and physical organs, and the South American natives chew the leaves, mixed with lime and the ash of a local plant. The drug is insidious and intoxicating, and many men become slaves to the habit, which shortens life. The official dose of cocaine leaves is ½ dr. to 2 dr. Of the various preparations of coca, the principal is coca wine, given as a nervine and muscular tonic. Of the alkaloids contained in coca, cocaine is the chief. It is used in dentistry as a local anæsthetic, being injected hypodermically into the gum; also externally for burns, insect bites, fevers, etc; and internally as a stomachic. The preparations from cocaine and its salts are very numerous. Antidotes to cocaine poisoning are amyl nitrite, nitroglycerin, digitalis, strychnine, ammonia, and strong coffee, and ether in hypodermic injections.

Cochineal—Cochineal is the name of a dye and of the insect from which that dye is made. This insect is the *Coccus cacti*, the chief sources of which are Guatemala and the Canary Islands. It lives upon several species of cactus, the principal being *Cactus nopal*. The insects are carefully reared, and the females are placed in gauze bags, which are hung around upon the leaves of the growing tree, the buds of which are removed as they appear, so as to give all the sustenance to the leaf growth. As the young insects are born they spread themselves over the leaves. When the time of spawning approaches they are collected into baskets, spread out on the ground or on trays for some time, then placed in heated ovens for a few hours, and finally thoroughly dried in the sun. Black cochineal and silver cochineal are the names given when differently prepared for the market. Cochineal is frequently impoverished or adulterated. Its chief use is in dyeing, although the coal-tar dyes have seriously impaired its value.

Cocoa—Cocoa, or cacao, is the pod fruit of an evergreen plant, *Theobroma cacao*, which grows in the West Indies, tropical America, Guinea, Ceylon, and elsewhere. [The manufacture of cocoa and chocolate has been described on page 6555.] The cultivation of cocoa demands care. The seeds are taken from the ripe pods, and are sown about 1 ft. apart in furrows 2 in. deep, and just covered with earth, on the top of which plantain leaves are spread. After two weeks, shoots will have appeared, and must be kept well watered until they are 14 in. or 16 in. high. Then they are transplanted to sheltered situations, where the soil is well irrigated. The cocoa-tree requires shade, and this is got by planting with them coral-bean trees, which grow much higher than the cocoa-tree. The trees must be pruned regularly, so as to develop a single stem with a full head. There are two harvests a year, in June and December; but in the tropics the fruit gets ripe throughout the year, and what is ripe is gathered fortnightly. The pods are detached with a knife on the end of a pole. The average yield is 6 lb. per tree per annum. Before being exported the pods are cured [see page 6555].

Coconut—The coconut, generally miscalled *cocoanut*, is the fruit of *Cocos nucifera*, a tropical palm, and must not be confounded with the evergreen *Theobroma cacao*, whose pod fruit is made into cocoa and chocolate [see above]. The coconut palm is found in nearly all tropical countries, and there is no single tree, except perhaps the bamboo, which is so generally useful. In the Pacific Islands, in the East and West Indies, and in tropical East and West Africa, the tree grows abundantly. The trees are propagated from the nut, and are planted during the first four months of the year, or in August. The situation should have sun exposure, and the patch of ground should be elevated, so that it may be drained naturally. The nuts are planted about 1 ft. apart in trenches, which are kept moist, but not wet. The shoots are transplanted from two to twelve months after their appearance. About the seventh year the tree begins to bear fruit, and attains maturity about the tenth year, and continues to yield fruit until the seventieth or eightieth year. The annual yield of a tree is from fifty to a hundred nuts. The kernel of the nut contains about 70 per cent. of fat, which, in the form of coconut oil, is largely used in soap manufacture [see page 4832] and for candles. In the West Indies, coolies eat the oil, using it as we use butter. The coconut palm can be diverted from bearing fruit by cutting off the flower stalks; then, by making an incision in the stump and beating it, the juice, which is called *toddy*, is made to flow. This is an esteemed beverage, but ferments quickly, and becomes very intoxicating after standing a few hours. It serves as yeast, and is extensively used by bakers in Ceylon and elsewhere. A sugar known as *jaggery*, and resembling maple sugar, is made from toddy, the unfermented juice being boiled to a syrupy consistency and poured into buckets, where it crystallises. This jaggery is a valuable article of food in some districts; and it has also a limited use in the manufacture of a cement, being mixed with white of eggs and the lime from burnt shells. This cement is highly tenacious, and, when polished, resembles white marble. The fibre that encloses the coconut comes into our market as *coir*. The fibre covering is removed from the nut before the latter is fully ripe, as, if allowed to remain, it becomes more coarse. It is then soaked, preferably in salt water, from six to eighteen months, or for a shorter time if tanks wherein the water is heated by steam be used. The husks are then beaten or crushed in a mill, and finally "willowed," when the fibre is ready for export. The chief use of the fibre is for press bags, used in oil refining, and candle making, for mats and matting, for cheap scrubbing brushes, for a coarse cordage chiefly used in the harvest field, and as a stuffing for cheap furniture. The bark of the coconut palm yields a strongly cohesive gum.

Cod-liver Oil—Cod-liver oil is extracted from the liver of the common cod (*Gadus morrhua*). The chief sources of cod-liver oil are Norway and Newfoundland, the former drawing its supplies of fish from the North Sea, and the latter from the Newfoundland banks. Great improvements have been made in the methods of extracting the oil, with good results regarding the purity and quality of the product. The livers must be fresh, not more than twelve hours after the fish is caught. Good, healthy livers only are selected, others being rejected. They are placed in tubs or open barrels, and as the oil exudes it is ladled off. The livers are then subjected to heat not exceeding 180° F., and more oil exudes. The oil is then subjected to extreme cold in chambers furnished with cylinders or pillars containing brine and snow. The portion that remains after reducing the temperature is drawn off, strained, and filtered, and constitutes the finest medicinal cod-liver oil. After the livers have been subjected to the natural expression described above they are heated again, which causes a further expression, the result being a darker coloured and slightly inferior oil, which is still, however, used medicinally. After this treatment the livers are boiled down, and yield the dark brown cod-liver oil used by tanners and for fattening cattle. The refuse livers are used as manure, and are added to other refuse matter in the manufacture of what is called *fish guano*. Other fish besides the cod—the ling, the turbot, the haddock, etc.—yield oil, which is sold as cod-liver oil, but no oil other than that from cod livers is regarded officially as cod-liver oil. Cod-liver oil has nutritive properties, and is also an active alterative; it is extremely valuable in cases of phthisis. Some stomachs reject it or accept it with difficulty, hence it is frequently given as an emulsion made by mixing with yolk of eggs, water, and other ingredients.

Cola Nuts—See *Kola Nuts*.

Colocynth—Colocynth, or bitter apple (*Colocynthidis pulpa* of the British Pharmacopœia), is the dried pulp of the fruit of *Citrullus colocynthis*, a creeping plant of the cucumber family that grows in Asia, North Africa, and some parts of Europe. When fresh, the fruit is green, but is yellow-brown when dried. Turkey colocynth is considered better than Spanish colocynth, although its superiority has not been established. The official dose is 2 gr. to 8 gr. It is a frequent ingredient in aperient pills, and is a drastic cathartic. The active principle of colocynth is *colocynthin*, a glucoside in the form of an amorphous yellow powder (dose, fifteen minims of a 1 per cent. solution in glycerin).

Copal—Copal resins, much used in the manufacture of superior varnishes for outdoor use, include East African copals, American copals and Kauri, Cowrie or New Zealand copals [see page 1034].

Coral—Coral is formed by some of the marine animals known as *Cœlentera* (meaning hollow-bodied), which have the power of absorbing lime from sea-water, and of building up therewith limy skeletons. These limy skeletons in the mass form what we know as coral, of which there are numerous varieties. The delicate pink coloured coral is the most esteemed variety, and is the dearest. Then there are red, black, and dull-white corals, all of them divided again into several varieties, usually according to colour. The chief sources of commercial coral are along the coasts of Italy, in Dalmatia, and in Algeria. The sole use of coral is for purposes of

ornament, particularly for manufacture into beads, which is an important Italian industry.

Cotton Wood—See *Poplar.*

Cudbear—See *Archil.*

Currants—The dried currants of the grocery shops are small seedless grapes, grown in Greece and the Levant; they are dried and trodden into casks. The name *currant* is a corruption of Corinth, from the district around which they have always come. The currant grape is also grown in Italy, and made into certain kinds of Italian wine. The currant of Greece must not be confused with the berries grown in English gardens, of which there are three varieties—the red currant (*Ribes rubrum*), the white currant (*Ribes album*), and the black currant (*Ribes nigrum*). Black currants make the most profitable market crop. The young shoots are those which carry fruit, and every year all the dead wood and much of the old wood should be cut away. Only as much of the young wood should be cut as will prevent overcrowding of the shoots. In red and white currants slightly different conditions prevail. The young wood should have much more cutting, and the old wood much less, as the latter carries the berries. In May the new shoots should be cut to five leaves, and in the following November to two buds, at which time also the leading shoots should be cut down to six inches long. Bushes without branches in the centre yield the best crop. All three varieties do best in fairly rich soil deeply trenched.

DAMMAR—Dammar is the name applied to a number of resins the chief of which is *Singapore dammar* or *white dammar*, the resin of the Amboyna pine (*Dammara orientalis*), of Java and Malacca. Dammars are used for varnishes and for making sticking plaster.

Damson—The damson is a small, hardy plum largely grown in England, and originally imported from the Levant. The name is a corruption of Damascus plum. It is used for cooking and preserves, and for a pressed conserve called *damson cheese.* The mountain damson, or bitter damson of the West Indies, is the *Simiruba amara.*

EBONY—The name ebony is properly applied only to the heartwood of the trees of the genus *Diospyros*, but it is frequently applied loosely to any hard black wood. The best black ebony comes from India, Ceylon, and the Malay Peninsula (*Diospyros ebenum*). The heartwood is quite black, while the sap wood is white; the latter is removed before the logs are shipped. *Green ebony*, so-called, comes from certain of the West Indian islands, and *red ebony* from Madagascar and Mauritius. Jet black ebony is the species most highly valued. It is used chiefly for inlaid work, and for small turned articles. [For the strength of ebony, see page 1260.]

Elm—There are many varieties of elm; four are found in Great Britain and two are abundant, the common elm (*Ulmus campestris*), and the wych elm (*Ulmus montana*). [For the physical properties and strength of elm see pages 53 and 1260.] Elm is largely used for piles and other work under water. Old water conduits are found to be elm trees hollowed out into cylindrical shape. Elm, however, decays where it is wet and dry frequently in succession. It is also a favourite wood for making coffins. *Spanish elm* is a West Indian wood (*Cordia gerascanthus*), the timber of which is also known as *Prince wood.*

Esparto—Esparto, or alfa (*Stipa tenacissima*), is a grass that is extensively used in paper-making in this country, although it is used for this purpose nowhere else. It grows in Spain, Portugal, Greece, North Africa and elsewhere. It is hardy and can be cultivated in England. The grass grows in tufts and the interior of the leaf sheath is hairy [see page 6280]. The best localities for esparto are on the sea coast facing south and at moderately high altitudes. Chalky soil is best and clay is unsuitable. It is twelve years after sowing before the plant becomes profitable. The most profitable propagation is by burning down the annual flower stems, and a good crop is got five or six years later; but this method is possible only on old esparto land. One acre may give ten tons of the grass. Harvesting can be done only in dry weather, when an experienced man can pull the leaves from the stems, leaving the latter uninjured to develop fresh leaves again. In addition to paper-making, esparto is used for cordage, sieves and baskets, and in upholstery.

FLAX—The uses of flax (*Linum usitatissimum*) have been discussed elsewhere [see General Index]. The seed of the plant—*linseed*—is chiefly used for the oil it contains, which is expressed from it, and which is used as a vehicle for paint, as a cattle medicine and in linoleum manufacture. The residue from the oil-press is made into cake and is a valuable cattle food. Crushed linseed—the *linum contusum* of the British Pharmacopœia—is used medicinally chiefly for poultices, and flax seed is also sometimes given internally for habitual constipation, a teaspoonful floating in water being taken before breakfast. Carron oil, used as liniment for burns, is a mixture of linseed oil and lime water in equal parts.

Freestone—See *Peach.*

GAMBOGE—Gamboge is a gum resin from a tree (*Garcinia morella*) that grows on the coasts of Ceylon, Cochin China, and elsewhere in Asia. The bark is incised as soon as the flowers appear and the resin exudes. It is imported in the form of solid and hollow cylinders, and in cakes; the most esteemed variety being Siamese gamboge in the form of pipes. The chief purpose of gamboge is as a pigment, but it is also used medicinally as a purgative. It is an official preparation in India and the Eastern Colonies.

Gooseberry—The gooseberry (*Ribes grossularia*) grows wild in temperate Europe and in Western Asia, and has of recent years been introduced and successfully cultivated in the United States. It is a hardy plant and grows better in the north of Britain than in the south. The soil should be fairly heavy, deeply dug, and well manured. Full grown bushes should be 5 ft. or 6 ft. apart. The plants are usually reared from shoots, which ought to be cut in September and should be not less than 12 in. long. Cut off the tops of the shoots and plant with about 4 in. showing above ground. Pruning should be attended to, old wood cut away as new shoots appear, and cross branches removed with the knife. The pruning should be sufficient to allow sunlight into the middle of the bush and to permit entry of the hand for picking. Young bushes will yield a crop of about three tons to the acre and after three years quite six tons.

Grape Fruit—See *Shaddock.*

Graphite—Graphite is frequently miscalled plumbago or blacklead, an error which has arisen from the supposition that lead was one of its constituents. It is a native form of carbon, and is found in the form of masses or sheets with mica schist, granite, and other minerals. Its geographical distribution is very wide, and it occurs generally throughout the globe. The only known deposit for many years was at Keswick, in Cumberland, and the mines there were worked to enormous profit for a long time. The chief sources at present are Siberia and Ceylon, the principal known deposit in the former country being in the hands of Faber, the famous German pencil-maker. Apart from the manufacture of lead pencils, graphite finds its most important use as a material for crucibles, and is also used as a dry lubricant, and as a stove polish. It is used also in electrotyping and as a conductor in electrical work. It is manufactured artificially by heating coke in the electric furnace.

Greenheart — Greenheart (*Nectandra rodiæi*) is a tree of British Guiana. It is highly esteemed for its strength, elasticity and enduring properties [see pages 57, 1260 and 6497]. From the bark, which is known as *bibiri* or *bebeeru* is prepared *buxine* or *pelosine*, a sulphate of beberine, used in medicine as a tonic and febrifuge (dose 1 grain to 10 grains).

Ground Nut—The ground nut, also known as the pea-nut, or monkey nut, is the nut of a low creeping plant, *Arachis hypogœa*, which is extensively cultivated in India and the Malay Peninsula, Africa, and America. The nuts are nutritious, and are much eaten in America, being usually roasted. The most economical method of extracting the oil is to clean the nuts, remove the shells, and winnow the kernels free from shells and dirt. The oil is then pressed out cold, after which the residue is finely ground and put under great pressure under steam heat, yielding an oil of an inferior quality. Sometimes there are three expressions yielding respectively a culinary oil, an illuminating and wool-dressing oil, and finally a coarse oil suitable for soap-making. Nut oil is often substituted for olive oil.

Guaiacum—See *Lignum Vitæ.*

Guano—Guano is the excretion of sea fowls, such as sea gulls, penguins, cormorants, and its value as a manure is due to the fact that it contains the most valuable constituents of plant food in a form that can be readily assimilated by the plants. The precise composition of guano depends upon the locality from which it has come, upon the animals or birds responsible for its production, and upon the food of these birds or animals. The chief constituents are nitrogen and phosphates. Nitrogenous guano comes from hot, dry countries, and phosphatic guano from damp countries; the former variety is the more valuable. The best supplies have come from the Chincha and other islands off the Peruvian coast, and less valuable supplies from Patagonia and West Africa. The known supplies of guano are fast becoming exhausted. Artificial guanos are manufactured chiefly from fish and fish offal. Norway has many guano manufactories, making guano from fish.

Guinea Corn—See *Millet*.

Gums—A gum is a substance obtained from plants, and capable of solution in water, so as to form a sticky fluid with more or less adhesive properties. Various so-called gums used in varnish-making and for other purposes are not gums proper, being soluble in alcohol and not in water; they are properly resins [see *Resins*]. The most common gums proper are gum arabic or gum acacia (which constitutes quite a class derived from several sources), gum tragacanth, agar-agar and Iceland moss. Gum arabic is the exudation from the stems and branches of *Acacia senegal* and of other species of acacia. It occurs in the form of round or ovoid tears or irregular masses, and is yellowish in colour or almost colourless. The trees which yield it grow in Egypt and the surrounding districts. The last variety is generally called *gum senegal*. The *mucilage of acacia* of the British Pharmacopœia is made by dissolving 4 oz. of gum acacia in 6 fluid ounces of water. It has a limited use in medicine, not for its medicinal effects, but because it enables other drugs to be held in suspension or in cohesion. Ordinary office gum is made with gum arabic, but is frequently adulterated with or replaced by dextrin. Gum arabic is also used extensively in certain branches of the textile trades. *Gum tragacanth* comes from Asia Minor and Greece. It is the exudation of *Astragalus gummifer*, and has stronger cohesive properties than gum acacia. *Agar-agar* is a seaweed (*Plocaria lichenoides*), found in China and Malaya and is used for jellies, paper varnish, and other purposes. *Iceland moss* is a lichen found in Iceland and North Europe, and is used for similar purposes.

HAZEL—The hazel (*Corylus avellana*) is a common British shrub. It is too small to yield timber of commercial value, but the wood is used for garden furniture, and forked hazel twigs are the common divining rods used by those with the mysterious ability to find water by their means. Hazel nuts are esteemed as a dessert fruit. They yield an oil by expression, and this oil has a limited use in perfumery.

Hemlock—The common hemlock is a native British plant (*Conium maculatum*), of the order *Umbelliferæ*. It is a tall plant having a smooth stem with purple markings, and finely cut, glossy, green leaves. It has a strong objectionable odour and is a poisonous plant. It is used medicinally, usually in the form of a tincture, its action being to paralyse the respiratory centres and the motor nerves. In addition to the hemlock plant which grows in this country, the name is applied to certain North American trees, which are used locally as a building timber. Hemlock bark, so-called, is obtained from one of these trees (*Abies canadensis*), and is a very important tanning material in Canada and the United States. It contains from 7 per cent. to 10 per cent. of tannin and produces a leather of reddish colour. Hemlock extract, containing about 30 per cent. of tannin, is made from the bark and is exported from Canada to the United States and to Europe.

Henbane—Henbane grows in England (*Hyoscyamus niger*) and throughout Northern Europe and Asia. It is a tall herb with large hairy leaves and a pungent odour. Extract of henbane is used in medicine (dose 1 gr. to 2 gr.), and is a hypnotic and narcotic. It contains the poisonous alkaloids *hyoscyamine* and *hyoscine*. The antidotes are the same as for belladonna [see *Belladonna*]. Numerous medicinal preparations are made from henbane.

Henequen—See *Sisal*.

Holly — The common holly (*Ilex aquifolium*) is a well-known hedge tree, growing very close, though slowly. The red berry makes the holly an esteemed decorative tree. From other varieties of holly, which are widely distributed throughout Europe and North America, the holly wood of commerce is obtained. It has a fine close grain, is tough and hard, and is used for cog-wheel teeth, and in cabinet-making.

Horn—Horns are important articles of commerce although many of the manufactures for which horn was formerly the sole material are now made of metal, celluloid and vulcanite or hard rubber. Horns are imported into Great Britain from many countries, the chief being France, Germany, and the Argentine Republic, although none of these supply so much as our own India. The most valuable horns imported and used in manufactures are those of the Brazilian ox, the Cape buffalo, and the Arnee buffalo of India. The most important uses of horn are for combs, for buttons, and for handles for cutlery, umbrellas, and walking-sticks. The horn is prepared for comb manufacture by being softened in water and then in acid; it is then split or sawn into thin pieces, which are subjected to hydraulic pressure. Pieces of horn may be joined together by pressure and heat, and no evidence of the junction will be revealed. Horn may be dyed as desired [see page 6767].

Hyssop—Hyssop (*Hyssopus officinalis*) is cultivated in the South of France. It is a hardy plant, aromatic and bitter. The leaves are used to flavour salads, and are one of the ingredients in the beverage absinthe. The dried flowers are medicinal. An essential oil is obtained by aqueous distillation.

ICE—Ice is a natural product, imported into this country in considerable quantities from Scandinavia. The imports have fallen since ice began to be manufactured artificially. When the ice on the Norwegian lakes is about 12 in. thick it is cut. First an ice plane drawn by horses is passed over it, and then parallel and equidistant grooves are cut with a hand plough, and deepened with an ice plough. A saw is used to remove the first few blocks and the remainder are detached with the help of special breaking bars. The blocks are then floated to the ice-house or to the place of transport, during which they are generally protected by pine shavings.

Indian Hemp—Indian hemp, the *Cannabis indica* of the British Pharmacopœia, is the dried flowering or fruiting tops of *Cannabis sativa*, which grows in Northern India. The herb is an annual, 8ft. to 10 ft. high. The form in which it reaches the western market is a compressed mass, consisting of the stems, leaves, and fruit, matted together with the natural resin of the plant. The official dose of the bark is 5 gr. to 15 gr.; the pharmaceutical preparations made from it are an extract, a fluid extract, a draught, a tincture, and pills. It is narcotic and anodyne, and is given for hysteria, asthma, and migraine. Overdoses are poisonous, although no death from it is on record. The antidotes for it are the stomach pump, emetics, stimulant draughts, artificial respiration, and coffee. Indian hemp induces dreams; is the *hashish* of Alexandre Dumas; and the *bhang* of India.

Indigo—The uses of the dye indigo have been discussed elsewhere [see page 5781]. The cultivation of indigo is an important Indian industry, although the synthetic manufacture of indigo [see page 5463] has inflicted great injury to the cultivation of indigo. Many plants in many tropical and subtropical countries yield indigo; but the most important is *Indigofera tinctoria*. The best soil is rich loam, alluvial for preference. Ploughing takes place in October and November, and sowing in February, March, and April. The harvest is in July, August, and September, when the blossoms are full. The dye is generally prepared by the green leaf process. In this process the plants are cut down and put into tanks, being held down by beams placed on top of them and athwart the vats. They are covered with water and allowed to steep from ten to sixteen hours, the duration depending upon the weather. Men then go into the tanks and agitate the contents for from two to four hours, until the fecula begin to separate and settle and the colour of the water changes from green to blue. More water is added, and this hastens the deposition of the fecula, and after a few hours the water is run off from the top, leaving the deposited fecula, which is then taken and boiled for about six hours under continuous stirring. The contents of the boilers are run off into strainers, and after about twelve hours the remaining mass is pressed, cut, stamped, and dried, the final product being the indigo of commerce. Other sources of indigo, besides India, are China, Japan, Siam, the Philippines, Java, and some South American countries.

Ipecacuanha—The drug known under this name is the root of *Psychotria ipecacuanha*, a shrub growing in South America and the East Indies. Its uses in medicine are as an expectorant and an emetic. It is a favourite remedy for croup and other diseases of children, being given generally as ipecacuanha wine (adult dose 10 drops to 30 drops as an expectorant, and 4 drachms to 6 drachms as an emetic). The dose of the powdered root is ¼ gr. to 2 gr. as an expectorant, and 15 gr. to 30 gr. as an emetic. The drug contains two alkaloids, *emetine* and *cephæline*, and powders and other preparations from which the former is extracted, are given for dysentery. Extracts, tincture, syrup, and pills of ipecacuanha are also made.

Irish Moss—Irish moss, or Carrageen, is a seaweed (*Chondrus crispus*) the commercial sources of which are the west and north-west coasts of Ireland and a small part of the coast of Massachusetts. In America, whence comes the greater quantity, the moss is pulled from May to September, boats being used to reach the rocks. Spring tides are usually chosen for the pulling, as the ebb of the tide leaves more rock surface uncovered then. The moss is bleached in the sun, washed repeatedly in salt water, and dried. Irish moss is used medicinally for jelly for consumptives, and as a decoction flavoured with sugar and lemon juice it is demulcent and nutritive. It is also used for refining beer, and the poorer qualities for making size for cotton and paper. Sometimes it is fed to cattle.

Istle—See *Sisal*.

Ivory—True ivory is the tusk of the Indian and African elephant. When

the elephant is tamed, the tusks decrease in size and deteriorate in quality, hence the tusks of the wild elephant form the best ivory. The African elephant usually possesses larger tusks than the Indian elephant. The former have yielded tusks up to 200 lb. weight, and even heavier, but the latter seldom show more than 70 lb. weight. The use of ivory has diminished for cutlery hafting, billiard balls, etc., since xylonite or celluloid appeared on the market. Tusks that are only slightly curved are preferred to those with sharper curves and twists. *Fossil ivory* or *mammoth ivory* is a true ivory from the ice-preserved remains of the extinct mammoth elephant *Elephas primigenius*, and is found within and near the Arctic circle of the three northern continents—notably in Siberia. The largest variety—supposed to be the tusks of the male—are about 9½ ft. long, and a smaller variety—supposed to be the female—about 5½ ft. long. These are true ivories; there are other so-called ivories that are not true ivories. *Walrus ivory* is the tusks of the walrus or sea horse, and is obtained chiefly in Alaska. These tusks are sometimes as long as 2 ft., and usually weigh about 2 lb. each. They are coarser than elephant and hippopotamus ivory, and commercially are of less value. *Hippopotamus ivory* is the tooth of the African hippopotamus. It is harder than elephant ivory, less liable to stains, and of delicate whiteness, but it is inclined to be brittle. The supply is small. Hippopotamus ivory is used for the handles of surgical instruments and for other purposes for which elephant ivory is employed. *Narwhal ivory*, sometimes wrongly called *swordfish horn*, is the tusk of the male narwhal or *sea unicorn*. It is obtained as long as 10 ft. It is the supposed *unicorn's horn* esteemed in medicine a few centuries ago. The supply is small, the quality coarse, and the value low. *Dugong ivory* is the tusk of the Australian dugong or sea cow. Only the male has tusks, and these have a value as ivory. The supply is small. *Vegetable ivory* is the albumen of a South American nut [see page 812].

JACARANDA WOOD—See *Rosewood*.

Jalap—Jalap is the tuberous roots of *Ipomœa purga*, a Mexican plant, which also grows in Jamaica and India, and even in the South of England. The roots are dug up and dried, the larger ones being sliced open to hasten the drying process. The dose of the powdered root is 5 gr. to 20 gr. Its effect is purely purgative, and it is much less used than it was a generation ago. It is also administered as a tincture, as a compound powder, and as an extract.

Jarrah — Jarrah (*Eucalyptus marginata*) is the best known of the West Australian hard woods, and is extensively used in this country for paving blocks. It is also used for piles and railway sleepers, as it is very durable, and has the property of resisting attack by animal organisms that destroy most other woods. The tree grows to a great size, so that large planks can be obtained. The Karri (*Eucalyptus versicolor*) is closely allied to Jarrah, and is also from Western Australia. It has similar uses.

Jet—Jet is a variety of lignite or brown coal which has turned black by fossilisation, and it was formerly extracted from the Upper Lias shales near Whitby. It occurs also in other countries—notably Languedoc in France, Galicia, and Massachusetts. The harder pieces are the jet, which is cut into beads and other ornaments. These are intensely black, and take a high polish. Jet, as a material for ornaments of personal adornment, used to be much more fashionable than it is to-day.

Job's Tears—See *Millet*.

Juniper—The common juniper is an evergreen shrub (*Juniperus communis*) which is indigenous in Great Britain and North Europe. The fruit of the juniper—juniper berries—is used in the manufacture of gin. Raw grain spirit is flavoured with the ground or crushed berries, or bags containing juniper berries may be suspended in the still, this being held to yield the better product. Holland is the chief seat of gin manufacture, the centre of the industry being Schiedam, where the world-famed schnaps is distilled. British gin—so-called—contains no juniper berries, being merely grain spirit flavoured with turpentine. Oil of juniper is a volatile oil obtained from the berries by distillation, and is of greenish-yellow colour, and of a turpentine taste. It is given medicinally (dose 5 min. to 20 min.) as a diuretic and for kidney troubles. A variety of juniper (*Juniperis oxycedrus*) yields oil of cade, which is used as an external application in diseases of the skin, including eczema. Sandarach [see *Sandarach*] is frequently erroneously called *gum juniper*. The so-called cedar wood used for lead pencils is the wood of *Juniperus bermudiana* [see *Cedar*]. Virginian red cedar is the timber of *Juniperus virginiana*, and is much used for furniture on account of its immunity from attack by insects.

Jute—The treatment of the jute fibre in the textile industries has been considered elsewhere [see General Index], and the remarks in this place will concern only the cultivation of the plant. The two jute plants cultivated for the fibre are *Corchorus capsularis* and *Corchorus olitorius*. The chief seat of the jute cultivation is India, especially Bengal, although China and the Malay Peninsula are also not unimportant sources. The former plant is the larger, although both are of equal industrial value. They are annuals, and are most successfully cultivated in a loamy soil and in a hot damp climate. The sowing season is from the middle of March to May. The flower is yellow. When from 5 ft. to 10 ft. high, and in flower, the plants are cut down, the harvest being from July to October. In cutting, a sickle may be used, or the plants may be uprooted entire. Bundles of stalks are immersed in stagnant water to rot, and remain there from a few days up to a month. This separates the inner bark from the rest of the stem, and the inner bark is that used industrially. The final separation of extraneous matter is effected by manual labour, a man standing in the water and pulling off the bark in long lengths. After washing the fibres, the water is wrung out, the fibres are hung up to dry, and are finally packed in hanks and bales for export or for the factory.

KARRI—See *Jarrah*.

Kauri Pine, or Cowrie Pine—This timber (*Agathis australis*), is the most important exported from New Zealand, and constitutes the greater part of the timber exported from the new Dominion. It is found in the extreme north of the colony, and also in the district around Auckland. It is a tall tree, growing to the height of 160 ft., with a straight, smooth trunk rising 100 ft. before the first branch is reached. Its diameter is from 5 ft. to 15 ft. The grain of the wood is straight; the wood is easily worked, is sound, and free from knots, and can be highly polished. The great length and breadth of the planks obtainable from the tree added to the qualities mentioned, make it a very valuable wood for many purposes. Its length makes it fitted for ship masts, and it is also used for ship decks, flooring, and general house work, vehicles, furniture, and paving blocks. It has also been used for church fittings. [For its strength compared with other woods, see page 1260.] Kauri gum [see page 1034 and 5123] is a valuable resin used for varnishes and in linoleum manufacture. It is found chiefly as a fossil gum in ground where the tree has grown during thousands of years. A small quantity of the gum is obtained from growing trees.

Kola Nuts—Kola or cola nuts are valuable on account of their active principle, the alkaloid *caffeine*, which is also found in coffee. There are two trees that yield kola nuts, the *Cola acuminata* and *Cola vera*, both being native to tropical Africa and the latter being the more valuable. The nuts are chewed and eaten by the natives on account of their sustaining and stimulating properties. The alkaloid caffeine stimulates the heart, raises arterial tension, and keeps off fatigue; it is given as a diuretic, and for kidney troubles and typhoid (dose 1 gr. to 5 gr.). Antidotes to caffeine poisoning are the stomach pump and emetics.

LARCH—The larch (*Larix europœa*) is a valuable timber. [For its cultivation, see page 4679; for its properties and uses, see page 55; and for its strength, see page 1260.] The bark of the larch is used as a tanning material, and is valuable for light leathers. It contains about 11 per cent. of tannin. *Venice turpentine* is the exudation of the larch. Incisions are made through the bark of the tree, usually about the end of March, and the turpentine flows during the summer.

Lavender—Lavender is the flowers of a hardy perennial herb (*Lavandula vera*), cultivated at Mitcham and elsewhere in the South of England, and in Southern Europe. The dried flowers constitute the lavender of commerce. They retain their perfume for a long period, hence their value. Oil of lavender is made from the female flowers by distillation. English oil of lavender commands a much higher price than foreign oils, due to the care with which the plant is cultivated and the oil expressed. The first oil expression is used for the manufacture of lavender water, and the later expression for soap perfumery. The oil from the male lavender (*Lavandula spica*) is known as *oil of spike*, and its chief use is for artists' colours.

Lemon—The lemon is the fruit of *Citrus limonum*, a small tree of the orange family. The tree is about 12 ft. high, and thorny; it carries numerous branches, bearing oval leaves and five-petalled flowers. There are several varieties of lemon, including the citron, or Median lemon (*Citrus medica*), the pearl lemon (*Citrus margarita*), and the sweet lemon (*Citrus lumia*). The juice of the lemon has a distinct medicinal value, due to the citric acid contained. It is valuable in malaria and in scurvy, and has been given with good results in chronic rheumatism. Oil or essence of lemon is expressed or distilled from fresh lemon-peel. [See pages 4968 and 4969.]

Lignum Vitæ—Lignum vitæ is the heartwood of a West Indian tree (*Guaiacum officinale*), and is the heaviest and hardest wood known. The tree grows to a height of about 40 ft., and to a circumference of 4 ft. or 5 ft. Its branches are numerous and knotted. Jamaica is the chief source of the lignum vitæ imported into England. The wood is of a dark green or brown colour, freely streaked, and is so cross-grained that it cannot be split, and must be sawn or turned. Its chief use is for pulley blocks and rollers in machines of various kinds. [For its strength, see page 1260.] The resin of the tree—*guaiacum resin*—is used extensively in medicine (dose, 5 gr. to 15 gr.). It is used for rheumatism, lumbago, and diabetes. It is also administered as a tincture, a mixture, and in the form of tablets and capsules.

Lime—The lime tree (*Lilia europæa*) of North Europe must not be confounded with the fruit-tree described below. Our lime tree, the linden of Germany, is of rapid growth, and flourishes even in the dust-laden atmosphere of cities and towns. The trunk is thick, and the branches are slender, close, and upright. The leaves are large and flat, coming to an apex. The tree attains a great age, frequently over 1,000 years. The flowers are sweet-smelling, and contain honey, which attracts bees. The timber is white and close-grained, and makes a good carving wood. Acetic acid is obtained from it by distillation [see page 5465]. Basswood is the timber of the American lime-tree, and is common in Canada and in the eastern portion of the United States. Its nature and uses are similar to those of our lime tree.

Lime—The lime (*Citrus medica acida*) is a valuable fruit of the orange family that is extensively cultivated in the West Indies, and to a less extent in India and Burma. The common tree is very spiny, although one variety is spineless. It grows in poorer soil and in more exposed situations than the lemon, and the fruit is small—about one-third as large as a lemon. Lime-juice has anti-scorbutic properties, and by English law every ship must carry a supply, a precaution which has banished scurvy from our mercantile and naval marine. The juice is expressed by pressure, and is afterwards filtered and clarified. Sweet limes (*Citrus medica limetta*) grow in Southern India, and are not so highly esteemed as the common or sour variety.

Linseed—See *Flax*.

Liquorice—Liquorice is the root of *Glycerrhiza glabra*, a plant that is widely distributed throughout Southern Europe and Asia. The root enters our market in a dry state, and is sweet, mucilaginous, tough, and flexible. The root is manufactured into extract of liquorice, being crushed, boiled, and evaporated. The condensed juice—black or brown in colour—is rolled and stamped with the maker's name, and in this form comes to our market. The most esteemed brand is *Succus solazi*. The powdered root is the chief gredient in compound liquorice-powder, and several other preparations are used medicinally. Liquorice is a mild and agreeable laxative.

Litmus—See *Archil*.

Locust Beans—Locust beans are the pod fruit of the *Ceratonia siliqua*, or carob tree, common in Southern Europe and the Levant. They are the reputed food of John the Baptist in the wilderness, and are hence known as St. John's Bread. The chief sources of the locust beans imported into this country are Sicily and Southern Italy.

Logwood—Logwood is a tree (*Hæmatoxylon campechianum*) that grows in Central America. The heartwood is cut into chips, moistened and exposed to the air, when it undergoes fermentation and turns a deep red, and is then suitable for use as a dye [see page 5905]. A decoction and an extract of unfermented logwood are given medicinally for diarrhœa.

Loquat—The loquat (*Eriobotrya japonica*) is the Japanese medlar or quince. It grows in England in sheltered situations, but as it flowers in autumn it must be grown under glass if the fruit is to ripen. The fruit is of an orange yellow colour, small, round, or pear-shaped, and clustered. The flowers are white.

MAHOGANY—Mahogany (*Swietania mahagoni*) ranks pre-eminent among high-class timbers, in spite of many rivals to favour. There are two varieties of true mahogany—Spanish and Honduras mahogany [see pages 56 and 1260]. When the tree is cut, the wood is of a light reddish colour, but exposure to light darkens it. Honduras mahogany, known also as *baywood*, is not figured like Spanish mahogany, and is more brittle. The best Spanish mahogany is now used only as a veneer. The largest mahogany logs come from Mexico, but this variety is apt to be soft in the centre, and to develop star shakes. Other varieties of so-called mahogany come from India, and Africa. The mahogany-trees are cut in the height of the dry season—April and May—and after being squared and freed from branches and hauled to the rivers by oxen, are launched, made into rafts, and floated to the sea for shipment.

Maize—Maize is also known as Indian corn, and as mealies. It is the grain of a tall grass, *Zea Mays*. [For its cultivation, distribution, and food value, see the pages indicated in General Index.] Maize starch or cornflour is used as a substitute for arrowroot, and starch for laundry use is made from it by crushing it and allowing the starch to settle in water. Maize straw is used for paper-making. Maize oil is extracted from the grain by hydraulic pressure, and is used as a salad oil and in soap manufacture.

Manilla Hemp—The use and prospects of abaca or Manilla hemp (*Musa textilis*) have been discussed in the course on Textiles [see page 719]. The fruit of the plant is a non-edible banana, and the leaf sheaths furnish the fibre. The plant flourishes best on hillsides, and the atmosphere must be humid. The plant is propagated from root suckers or from seeds, the former taking three years to mature, and the latter about double that time. As the buds appear, the plant is cut down, the leaf sheaths are detached and split into layers and then thinned into strips about 2 in. wide and ¼ in. thick. Scraping removes the pulp, leaving the white strips ready to be baled for export. Owing to its strength, Manilla hemp is of great value as a cordage material.

Manna—Manna, a saccharin exudation from *Fraxinus ornus*, or the manna ash, comes to our market chiefly from Sicily, although it is also obtained in Southern Europe and Asia. It is obtained by incising the tree, when the manna exudes and hardens—at first, brown, but turning harder and whiter. Manna reaches us in the form of flakes, and indeed is known as *flake manna*. As a drug, it has mild laxative properties, but is not an official remedy in this country, although it is official in the United States. Dose, ½ oz. The manna of the Old Testament was probably the honey-dew of a Mediterranean scale insect.

Maple—The maple tree has many species. The common maple of our country (*Acer campestre*) is of no use for its wood. The maples of commerce come from North America, and the maple leaf is the Canadian national emblem. The beautiful deep and variegated hues taken on by the maple leaf in autumn give the Canadian woods a wonderful wealth of colour. The most important species of maple is the sugar maple (*Acer saccharum*), which yields maple sugar [see page 4351], the red maple (*Acer rubrum*), the silver maple (*Acer saccharinum*), and the broad-leaved maple (*Acer macrophyllum*). [For the uses of maple, see page 57, and for its strength, see page 1260.]

Mastic—Mastic is the resinous exudation from a shrub (*Pistacea lentiscus*) growing in the countries bordering the Mediterranean Sea. It is imported in yellowish or greenish tears and is used for varnish manufacture. It is also used, dissolved in alcohol, by dentists, being placed on cotton-wool to apply to the mouth during the application of an antiseptic. There are also an Indian and a Cape mastic of less importance.

Medlar—The medlar (*Mespilus germanica*) was once a more popular fruit than it is to-day. The flowers are large and white, with five-cleft calyxes and corollas, and the fruit is lemon-shaped. The tree grows best in heavy, moist soil, somewhat sheltered. The medlar is generally grafted on seedling medlar stock, or on pear, quince, or whitethorn stock. The fruit should be gathered at the end of October, and kept a few weeks before being eaten. The *loquat* is the Japanese medlar [see *Loquat*].

Meerschaum—Meerschaum is an earthy mineral, white or yellow in colour, and consists of hydrous silicate of magnesia. It occurs in veins or nodules, and the chief commercial source is Asia Minor. Before being exported, meerschaum is scraped to free it from the earth with which it is usually associated, then dried in the sun or in ovens, scraped again, and finally polished with wax. The common qualities are used in the manufacture of porcelain, and the best pieces are made into meerschaum pipes, principally in Vienna and Paris. The absorption by the meerschaum of oil from the tobacco causes the colouring of meerschaum pipes.

Millets—Certain cereal and forage grasses are known as *millets*. The importance of millets as food may be judged by the fact that about one-third of the world's population—chiefly Asiatic—eat it regularly. Sorghum, also known as *Guinea corn*, and in Egypt as *dhurra*, is a variety of millet. It is used in sugar manufacture [see page 3652], and as a cattle food. Young sorghum should not be given to cattle, as it has been proved to be poisonous, but the mature plant is free from poison. Job's tears, the fruit of *Coix lachryma*, which grows in India and Japan, is a variety of millet, and is used for ornamental purposes, chiefly for beads and mats. *Buckwheat*—erroneously named, for it is a small nut, not a wheat—is another millet, and is used as a food chiefly in Russia and in the United States.

Mother-of-Pearl—See *Pearl*.

Mulberry — The mulberry (*Morus nigra* and *Morus alba*) is a small tree

of the stinging-nettle order. The black mulberry yields a black, luscious berry. Planting should be done at the end of October or the beginning of November in well-drained soil. The young branches should be cut, leaving only four, and these should be cut back to 3 in. or 4 in., and to an outer eye.

Muscatel—See *Raisin*.

Mush-Mush—See *Apricot*.

Mushrooms—Mushrooms are a species of edible fungi of our woods. They can be cultivated in any situation with a uniformly warm temperature. Underground cellars make admirable mushroom beds, and in one case, at least, highly successful results are got by utilising a disused railway tunnel for the purpose. The temperature should be kept at about 50° F. The mushroom beds may be made in boxes or shelves, 2 ft. or 3 ft. wide, and ranged above each other against the walls. Dried horse manure, either alone or mixed with 25 per cent. (by measure) of loam, forms the best material for the beds. This is placed on the shelves or in the boxes to the depth of about 1 ft., and is pressed firmly down. The beds of manure will develop heat, and when this is subsiding, and is about 90° F., the spawn should be broken up into pieces about the size of walnuts, and placed in the bed about 6 in. apart. Eight days afterwards, a layer of heavy loam, 1 in. thick, or more, should be put on the surface and beaten down hard. About a month later the mushrooms appear. There are many more edible fungi in our woods besides the mushroom, but fear of the poisonous varieties prevents their use. Mushrooms, though edible, have no highly nutritious properties, and are therefore of small sustaining value as a food. *Truffles* are a variety of fungi that we import from Italy, preserved in oil. They are used for poultry stuffing and for sauces and soups. The *Morel* is another fungus used in sauce manufacture; it grows in England to a limited extent, but is cultivated in Italy, whence our supplies come.

NECTARINE—See *Peach*.

New Zealand Flax—See *Phormium*.

Nux Vomica—A small tree (*Strychnos nux vomica*) that grows in India, Ceylon, Persia, and North Australia yields the seeds known as *nux vomica*, which play an important part in medicine. The seeds are flat, circular, smooth, and drab coloured. From three to five are embedded in the pulp of the orange-like fruit. They are extracted, washed and dried in the sun before being exported. They are strongly poisonous. They are used for dyspepsia, heart weakness, as a general tonic and stomachic, and to increase nervous energy. The official dose of the powdered nut is 1 gr. to 4 gr., but the drug is usually given as a tincture or as an extract in pills. The alkaloid which is the active principle is the strong poison *strychnine*. It is so rapid in its action that antidotes are seldom of value. The antidotes recommended are emetics, followed by washing the stomach with permanganate of potash solution or Condy's Fluid and by 4 dr. doses of bromide of potassium. Artificial respiration should also be tried.

OAK—There are numerous varieties of the oak [for which see the pages indicated in the General Index]. The species of highest importance is the British oak (*Quercus robur*), which is found in Europe and Asia and grows almost as far north as the Arctic circle. As a timber, oak combines hardness and toughness, hence its value. The "wooden walls of Old England" were the battleships built of oak. The introduction of iron and steel for ship hulls deposed oak from its supreme position in shipbuilding work. The durability of oak, even under water, is remarkable. The oak grows to great age and attains great size. The Newland oak, in Gloucestershire, had a circumference of 45 ft., and the extent of the spread of the oak is proverbial. Oak is extensively used for furniture and for wainscotting. It darkens with age, due to the action of the atmosphere upon the gallic acid which it contains. The darkened effect may be produced very quickly by exposing the wood to the fumes of ammonia. Wood so darkened is termed *fumed oak*, and the process is common in furniture manufacture. Oak is given to warping, but all varieties do not warp equally [see page 53]. It rusts when in contact with iron. The wood contains acetic acid, and 7·9 per cent. has been distilled from it [see page 5465]. Oak bark has an extensive use in tanning. *Bog oak* is oak which has become blackened by the action of iron salts in peat mosses where it has lain. Its enduring qualities in such a condition excel those of the natural wood. There are numbers of so-called oaks found over the world—Indian oak applied to teak, African oak, a hardwood of tropical Africa, and others.

Olives—The olive tree (*Olea europæa*), of which there is over a score of varieties, flourishes in warm but not in tropical climates. Extreme heat is as fatal to its successful cultivation as is extreme cold. The chief centres of olive cultivation are the countries bordering the Mediterranean, and from these we import preserved olives and the olive oil of commerce. Olive trees have, however, been introduced into America, Australia, and other countries held to be suitable to the cultivation, and moderate success has attended these enterprises. The olive tree grows on poor soil, and may be successfully cultivated on ground quite unfit for other crops. The soil should be dry, calcareous, and rocky, and drainage must be good. Hillsides are favourite situations for olive trees, and they are frequently cut into terraces. Propagation is effected by cuttings, by planting the root suckers, by seeds, and by grafting. Good strong manures should be used in olive farming, and should be applied annually if the soil is very poor, or biennially if it be of fair quality. Fruit is borne in the third or fourth year if regular pruning has been practised during the preceding years. The olive is a small, fleshy fruit, about the size of a grape, and contains one large hard-shelled seed. The best olive oil is procured from olives that are gathered before they are fully ripe. Fully ripe olives yield more oil, but of a lower quality. In its wild state, the olive tree bears fruit only every two years; but by careful cultivation, and by gathering the fruit regularly before it is fully ripe, annual crops can be secured. The fruit should be gathered by hand. The practice of beating the tree to cause the fruit to fall is common in some places, but it does serious injury to the branches, and impoverishes the succeeding crop. The yield of oil is from 25 per cent. to 50 per cent. of the weight of the fruit. The fruit is crushed, the stones or kernels being sometimes broken, and sometimes not, and then put into bags, which are put under presses in a warm room, where the oil is squeezed out. The marc, from which the oil has been pressed, is mixed with boiling water, and again pressed, the second expression yielding an oil of inferior quality. Olive oil is also known as *salad oil*, although many inferior oils are also sold under the latter name. Olive oil is sometimes given as a medicine, on account of its nutrient and laxative properties. It enters into the manufacture of Castile soap. The residue, or marc, after the oil has been extracted, is a valuable cattle food, and is also used as manure.

Opium—Opium is the dried milky juice from the unripe seed capsules of the opium poppy (*Papaver somniferum*). The cultivation and preparation of opium is an important industry in India, but it comes also from Turkey, Persia, and China. Attempts have been made to cultivate the plant in Europe, especially in France, and some of these attempts have been successful, although not commercially so. Incisions are made in the unripe seed capsules with an instrument that will not injure the seeds, and the juice flows out and coagulates. After a few hours it is removed with a knife and placed in inclined trays to drain. It is then dried somewhat in the sun, and comes to the Western market as a stiff, cohesive mass of dark brown colour. Upon the awful results of excessive opium eating and smoking we need not enlarge. The habit is the curse of China, and even in this country excess in drinking laudanum and preparations of morphia is too common. The drug (dose ½ gr. to 2 gr.) is a valuable remedy for pain, checking inflammation and nervous diseases, and benefits sufferers from cough, diarrhœa and dysentery. The liniment is use for rheumatism, neuralgia and sciatica. Internally it is given in numerous forms, chiefly as a pill and as a tincture known as laudanum (dose 20 to 30 minims.). For smoking, opium must be specially prepared. Of the three alkaloids of opium—morphine, narcotine, and codeine—the first is the most important (dose $\frac{1}{10}$ gr. to ½ gr.). It is administered in over a score of different preparations in addition to the powder. For an overdose of opium or morphine the antidotes are the stomach pump and washing out the stomach with a solution of permanganate of potash, also hot coffee, ammonia, or ether. The patient should not be allowed to succumb to the sleep induced by the drug, but should be made to walk until the narcotic effect has subsided. To cure the morphine habit it is recommended that the morphine solution should be replaced gradually by sparteine sulphate, ¼ gr. increased to ¾ gr. four to six times a day. *Poppy oil*, or *maw oil*, is expressed from the seeds of the opium poppy. It is used for artists' paints, as a salad oil, and as fuel and for soap manufacture.

Oranges—The common or sweet orange (*Citrus aurantium*) is native to China, and was introduced to Europe by the Portuguese in the sixteenth century. The best orange of the common varieties purchased in English shops is the St. Michael, which is thin-skinned, pale, and juicy, and has very few stones. The orange tree is very prolific in fruit, a tree fully mature may bear 12,000 oranges in one year, and cases are on record where over 20,000 have come from one tree in one year. Orange blossoms are white and fragrant, and from them is extracted

the essential oil—oil of neroli; but the natural oil has been displaced by synthetic oil of neroli [see page 4971]. Orange trees attain a great age, living for over 150 years. They have been successfully reared in the South of England in protected situations, but the expense attending such ventures and the poverty of the results have discouraged their further prosecution. The best flavoured oranges do not reach this country, because imported oranges must have been pulled when not fully ripe, and before they have reached their highest excellence. The mandarin, or Maltese orange (*Citrus nobilis*) is grown in China, in Malta, in the Azores, and elsewhere. It is a small fruit of oblate spheroid shape, with a loose skin, which, when fully ripe, may become spontaneously detached from the interior, allowing the latter to be shaken about loose within it. The fruit is exceedingly sweet, but does not keep so well as other varieties. Tangarine oranges are a variety of mandarin oranges. They are suitable for hothouse cultivation, and are prolific. The tree is small, being seldom higher than 7 ft. even in North Africa, the headquarters of their cultivation. Other varieties of the sweet orange are the Maltese blood oranges, a fine, large oval, rich blood fruit with dark red pulp; Majorca oranges, a seedless variety; Jaffa oranges, and a small kind known as *Kum-quat*, and coming from China and Japan. Seville or bitter oranges (*Citrus aurantium bigaradia*) are chiefly used for making marmalade. They are bitter, especially the rind, which is rugged and uneven. The fruit is round and dark coloured. The liqueur *Curacao* has bitter orange as one of its chief ingredients. The peel is pounded in a mortar under water, and after standing some time is distilled with alcohol. Sugar is added, and to some brands a special variety of rum. The rind of the bitter orange is also used for making candied peel [see page 4848]. Another bitter orange (*Citrus aurantium bergamia*) is grown in the South of France and in Sicily. Its only present use is for the expression of oil of bergamot [see page 4970].

PEACH—The largest and most delicious fruit of the plum family. In the English peach this fruit reaches its highest excellence, due to the care expended on its cultivation in this country. It grows best in loamy and calcareous soil, and benefits by the application of vegetable manure. The wall upon which peaches are trained should have a south-eastern exposure. Planting should be done about the end of November, and pruning should be regular in January or February. The trees should be about 14 ft. apart, and the fruit should not be closer than 6 in. There are three varieties of peaches—*clingstones*, *freestones* and *nectarines*.

Pea Nut—See *Ground nut*.

Pearls—Pearls are produced in the shells of several varieties of molluscs upon the introduction of a grain of sand or other foreign particle within the shell. Chemically, pearls are carbonate of calcium, and are built up in exceedingly thin layers, which show their characteristic iridescence by the interference of light. Attempts have been made to cultivate pearls by introducing a particle of sand within the pearl oyster shell, and leaving the animal to do the rest; but these experiments have not been crowned with conspicuous success, and practically all the pearls of commerce have been produced without the assisting agency of man. The chief sources of the salt-water pearls, which are the most valuable variety, are the *Aviculidae*. The most famous pearl fisheries in the world are in the Gulf of Manaar, in Ceylon, and other fisheries are in the Persian Gulf, in Queensland, and in California. Fresh-water pearls are of minor importance, commercially. They are formed by the *Unionidae*, fresh-water molluscs. The rivers of Scotland were formerly of some importance in supplying pearls, and a few come from there now; but fresh-water pearl fishing is not a regular industry as marine pearl fishing is. Taking the Ceylon pearl fisheries as illustrative, the fishing lasts for only a few days annually, and native divers descend from boats, relieving each other frequently. The pearls are sorted out into well-defined classes, according to lustre, shape, and size. Some oysters have the interiors of their shells lined with the pearlous substance known as mother-of-pearl, and many of the fisheries are conducted for the mother-of-pearl only, although pearls are also got in these places in small quantities. The best mother-of-pearl comes from the fisheries of the coast of Queensland, and other important sources are the seas of the Indian and South Pacific ocean. Commercially, mother-of-pearl has a ide th buttons, studs, fans, and other articles as well as for inlay work. Artificial pearls are now an important article of commerce, and the best of them are made from the scales of the bleak fish.

Phormium—Phormium fibre, or New Zealand flax, is an important cordage fibre which will attain a higher place industrially than it holds to-day. It is soft, white, and lustrous, and its strength is said to be greater than hemp or flax. The percentage of fibre yielded by the plant is high, being as much as 15 per cent. of the green plant. The preparation comprises crushing between heavy rollers, pounding of the crushed leaves by beaters on a revolving drum, washing in running water, and drying and bleaching in the sun. [See also page 817.]

Piassava—Piassava, or piassaba, is the "bass" of our broom manufacturers, and is the most important material used for stable and street brushes. The fibres are black or dark brown, and reach this country in bundles. They come from the leaf stalks and leaf sheaths of large palms that grow in South America and tropical Africa; the best is Bahia piassava. The tree grows wild, and is propagated naturally by its nuts. It is not cultivated. The unopened leaves are enveloped by coarse fibres of chocolate colour, which the natives remove with axes. The fibres are then combed out, straightened, and cleaned—all simple manual processes—and finally packed in bundles of about 30 lb., which again are made into bales of 80 lb. to 100 lb. for shipment. Locally a rope is made from the fibre, but its only use in Europe is for brushes. Para piassava is another variety from Para. African piassava and Madagascar piassava are coarser. [See also page 6106.]

Pimento—Pimento, or allspice, is the dried unripe fruit of *Pimento officinalis*, a tree that grows in the West Indies, Mexico, and South America. The chief source is Jamaica. An illustration of pimento appears on page 4720, and a brief account on page 4722. The fruit consists of black or deep purple berries with a smooth and glossy exterior. It is picked by hand when fully grown, but before it is ripe, and is spread out on floors to dry, a process which takes about a week. The popular name of allspice arose from the fragrance of the berry being thought to resemble a blend of various other spices. The wood of pimento is used for walking-sticks and umbrellas.

Pineapple—The fruit known as the pineapple grows on a tree (*Ananas sativa*) native to tropical America. To successful cultivation a long hot summer and absence of frost in winter are essential. Most of the pineapples entering the British market come from the Azores. The fibre of the plant has a limited value for textile fabrics [see page 818]. The inhabitants of Formosa and China use it for a coarse fabric, and the Piña cloth of the Philippines is also made with it. The leaves of the plant are scraped with a piece of sharpened bamboo, or with the edge of a broken piece of pottery. The fibre is then washed and sun dried, issuing soft, white, flexible, durable, and water resisting. It is then spun and woven.

Pisang—See *Banana*.

Plane—The plane tree (*Platanus orientalis*) is a hardy tree, growing well in a city atmosphere. It has a smooth, grey trunk, with a bark that scales in flakes, and large five-lobed serrated leaves. The Western plane (*Platanus occidentalis*) is not quite so hardy. It is called *sycamore*, and sometimes *buttonwood* in the United States; but it is not the same tree as our common sycamore (*Acer pseudo-platanus*), which is abundant both in Europe and North America. All varieties yield a fine, easily-worked white wood, extensively used for general purposes.

Plantain—See *Banana*.

Plumbago—See *Graphite*.

Podophyllin—Podophyllin is the resin of the root of *Podophyllum peltatum*, a plant that grows in Canada and the Eastern States. It is the American mandrake, or May apple, and is sometimes called *vegetable mercury* from its value as a biliary purgative. It is given also as a laxative and as an aperient. Podophyllum comes to the drug market as flattened root stems, and the resin is extracted in the drug shops by precipitation by means of acidulated water from an alcoholic solution. The result is a greenish brown powder of a decided odour and acrid taste, soluble in aqueous ammonia and almost entirely in alcohol. The dose is ¼ gr. to 1 gr. It is made into pills, tablets, tincture, and extract.

Poplar—The most common varieties of poplars are the white poplar (*Populus alba*), the black poplar (*Populus nigra*), and the aspen (*Populus tremula*). The wood of the poplar is soft, has a fine grain and a silky appearance, and is easy to work. For strength of the wood, see page 1260. The *cotton wood* of the United States is a variety of poplar, and *yellow poplar* is a name applied to white wood.

Poppy Oil—See *Opium*.

Prince Wood—See *Elm*.

Prunes—The prune is a variety of plum. It is cultivated in America, France, and several Mediterranean countries. It is a hardy tree that flourishes in a rich, moist soil, but by suitable grafting it can be grown on other soils. Sun-dried prunes are picked when fully ripe; they are peeled, strung upon twigs, put into straw frames, and suspended in the sun. After a preliminary drying the

stones are removed, and the prunes are then made thoroughly dry in the sun. In France, prunes not yet fully matured are placed in boiling water, then transferred to baskets, and agitated till cool, then completely dried by exposure to sun heat.

QUINCE—The quince (*Cydonia vulgaris*) is a fruit similar to the medlar. It has been grown in the Mediterranean countries since pre-Christian times, and, while not edible on account of its bitterness, is extensively used in the manufacture of jelly. The word *marmalade* is said to be derived from *marmelo*, the Portuguese word for quince. It is also cooked with apples and other fruits. The tree is used as stock for pear-trees in this country.

RAISIN—Raisins are dried grapes. Sultana raisins come from Smyrna, and Damascus raisins from Damascus. Both are stoneless varieties, the latter being the larger. The ordinary raisins of commerce come from Valencia. The usual method of drying these varieties is to expose them to the sun and air, and then to spread them out in rooms, sprinkling them with aqueous solution of potash or soda, which causes the formation of grape sugar, the small sweet accretions found on the fruit as purchased. *Muscatels*, which come from Malaga, are a variety of raisin that are dried while still hanging from their branches, the leaves being pulled off and the branch cut half through until the fruit is dry and ready for packing.

Ramie—The three names *ramie*, *rhea*, and *China grass* are used commercially without distinction for two fibres. Rhea, or ramie, is the fibre from the stems of *Boehmeria nivea tenacissima*, a large plant of the nettle order. It grows only in hot climates. The related plant, *Boehmeria nivea*, grows in temperate as well as tropical climates, and is properly *China grass*. In China, China grass is prepared for the market by manual labour, the outer skin being scraped and washed. The process of degumming—the need for which has prevented ramie from taking a very high place among textile fibres—is usually carried out at the mills whither the fibres are sent. [See page 1390.]

Raspberry—The raspberry (*Rubus idæus*) is a well-known fruit that grows wild in temperate Europe and is also extensively cultivated. Shoots spring from the root every spring, bear fruit in the summer of the following year and die in the autumn. The soil should be well manured and deeply trenched. The plants are usually 2 ft. apart in rows, each row being about 5 ft. from its nearest neighbour. They may be tied up with stakes or trained to a trellis of wire running along the row. Pruning consists in removing the excess stalks, leaving from three to five of the best and in cutting off the growths that are not in a position to be supported. The canes are cut short, but not too short, in spring, and any side branches induced to carry fruit. Autumn fruiting raspberries are pruned differently; in January the canes are cut to the ground and in spring those that have sprung are cut, leaving not more than four. Do not shorten the canes at all as only the upper portion bears fruit.

Red Currants—See *Currants*.

Redwood—See *Cedar*.

Resins—Resins are thickened plant juices insoluble in water, but soluble in alcohol and oils. Substances from kindred sources and soluble in water are known as *gums* [see *Gums*], although many resins are known as gums. Resins are usually found in plants that yield essential oils; for instance, common resin, or rosin, is found in pine trees, the essential oil of which is turpentine. The principal resins of commerce are as follow: Resin, resin, or colophony [see page 1034], amber, gamboge, copal, sandarac, camphor, dammar, mastic, benzoin, and tolu. Particulars of these are given under their respective names. Shellac is also a resin, although it is produced as an incrustation upon certain trees by the help of an insect [see *Shellac*].

Rhea—See *Ramie*.

Rhubarb—Rhubarb is a perennial plant cultivated for its leaf stalks, which are used for making jam and wine. It is usually propagated by division of the root, and flourishes best in rich, deeply dug soil. It is often forced by being covered with flower-pots, which are covered with stable manure which ferments and supplies heat. The rhubarb of medicine is the root of a plant (*Rheum palmatum*), larger than our garden rhubarb. It is grown chiefly in China and Tibet, and although the most esteemed variety is known as Turkey rhubarb the name has nothing to do with its source. Attempts to grow medicinal rhubarb in Europe have met with some success. As a drug it is given in powder form (dose 15 gr. to 30 gr., or if repeated, 3 gr. to 10 gr.). Compound rhubarb powder is generally known as Gregory's powder. Rhubarb is also administered as extract, as pills, as a syrup, and as a tincture. Its effect is laxative, and it is freely given for stomachic disorders.

Rice—For the cultivation, preparation and food value of rice the pages referred to in the General index should be consulted. Here we shall mention only some of the uses of rice which are not mentioned in other pages. In Japan, rice straw, besides being used as cattle fodder, is plaited into hats and shoes for men and horses. The bran and dust are also used as cattle foods, as stated elsewhere. The chaff from rice forms a good manure. Rice powder, or *poudre-de-riz*, is sometimes deceptive as it is frequently merely finely powdered soapstone, although a genuine rice powder is also sold as a complexion powder. The Japanese make an alcoholic drink named *saké* from rice by soaking it and inoculating with the fungus *Aspergillus oryzal*, which produces a ferment, and after several processes of fermentation yields a beverage named as above, and containing about 13 per cent. of alcohol. The Chinese and the Malay natives also manufacture alcoholic beverages from rice. *Wild Rice* (*Zizania aquatica*), is a wild plant that is extensively found in America as well as in Asia. It flourishes in muddy soil under shallow water. Attempts to cultivate it by Americans have not been conspicuously successful, but, under the ægis of the Department of Agriculture, experiments are proceeding.

Rosewood—The rosewood of the cabinet-maker has nothing to do with the English garden rose, and derives its name from the odour resembling that of the rose to some extent. It is the timber of certain Brazilian trees, notably *Dalbergia nigra*. Other varieties of so-called rosewood come from Jamaica, Dominga, Burma and New South Wales. *Jacaranda* wood is a name sometimes applied to the Brazilian *Dalbergia*. Rosewood is hard and even in the grain, has a fragrant odour, and a colour ranging from purple-brown to black. It is a high-class wood in furniture-work and for piano cases.

SANDAL-WOOD — Sandal-wood is the heartwood of several species of *santalum*, and is esteemed for its aromatic properties and for the essential oil that it yields. The chief source is India, but it is also found on some of the Indian and South Sea Islands, and in Western Australia. The Indian tree is the *Santalum album*, and the forests where it is cultivated are usually Government reserves. After the tree is felled it is allowed to lie for some months, during which time white ants devour the sap wood, which is of no value. The heartwood is then cut up and conveyed into the stores. The chips from this cutting-up and the sawdust is used for essential oil distillation [see page 4970]. Sandal-wood is made into trinket-boxes in India, and is easily recognisable from its fragrance and dark cedar colour. It is also burned as incense in religious ceremonies. Sandal-wood oil is extensively used in medicine for chronic bronchitis and other diseases. It is given in a variety of forms.

Sandarach—Sandarach, also known as gum sandarach and erroneously as *juniper gum*, is the exudation of the North African tree (*Callitris quadrivalvis*), and is much used for fine varnishes. It is used as a varnish for coating pills.

Satinwood — Satinwood (*Chloroxylon swietenia*) comes from both the East and West Indies; that from the East is figured, while West Indian satinwood is not. It is a beautiful hard wood, of yellow colour, and is valued in cabinet work. It is not obtainable in large pieces, the usual size of log imported being about 10 ft. long and 7 in. or 8 in. square.

Senna—The leaves known as senna are used in medicine as a purgative. There are two varieties—Alexandrian senna, the leaves of *Cassia acutifolia*, which are collected by the Arabs in the neighbourhood of Suakim, and East Indian or Tinnivelly senna, the dried leaves of *Cassia angustifolia*, which are cultivated in Southern India and are longer, narrower, and lighter in colour than the Alexandrian senna. Senna is administered as an infusion, an elixir, a confection, and in other preparations. Compound liquorice powder is one-sixth part senna. The American medicinal drink known as Garfield tea contains senna.

Shaddock — The shaddock (*Citrus decumana*) is a large fruit of the orange family, and is largely cultivated in the Malay peninsula and Southern Asia, and in some of the Oceanic islands. It has a smooth, pale yellow skin, and a white or reddish pulp. It sometimes weighs from 10 lb. to 20 lb., the flavour resembles that of the grape, and hence it is often called the grape fruit. The West Indian grape fruit is another variety of the Asiatic shaddock.

Shellac—Shellac is the most common resin used for varnish manufacture, and is also used for sealing wax and forms an excellent natural cement. It is formed on the branches and twigs of a large number of Indian trees by the lac insect (*Coccus lacca*). The incrustations are removed and melted in boiling water, afterwards being poured upon a cold surface, where they take the form of thin, irregular flakes. *Ground shellac*, also known

under half-a-dozen other names, is the resin of the Australian *Xanthorrhœas*. It is used for varnish, for staining wood, and also in the manufacture of picric acid.

Sisal—The fibre known as sisal hemp ranks second only to Manilla hemp as a strong cordage fibre. There are two varieties of sisal, the *Agave rigida elongata* of Yucatan, and the *Agave rigidi sisalana* of Florida, Cuba, and the Bahamas. The latter is the more important, and is known also as *henequen*. The sisal has recently been introduced into India and British East Africa, and the foundations of new industries laid in these colonies. The plant flourishes in any stony soil rich in limestone. The treatment of the growing plants and of the fibre-yielding leaves is similar to that of Manilla hemp. After preparation, the fibre is a straight, pale yellow ribbon from 2 ft. to 4 ft. long. Other plants of the same order are the *American aloe* or Century plant, the *Istle* or Mexican fibre, and Mauritius hemp. These are inferior to the true sisal.

Slate—Slate is a clay that has been folded and compressed in its bed, so that it can be split readily into thin and uniform plates. Slates differ in colour according to locality. The slates of the Lake District are greenish; Cornwall slate is grey. The best known slate quarries in this country are the Penrhyn quarries near Bangor, in North Wales; in Scotland the most important source is Ballachulish, and in Ireland, slates are obtained at Valentia and Killaloe. Slate is obtained by sawing large blocks in their beds, and these are sawn up into lengths, either machinery or hand saws being used. Slate splitting is done by hand, the tools employed being thin, broad-faced wedges and wooden mallets. In winter-time slates may be split by the natural action of frost, water being poured over the blocks, and when this expands by freezing fracture occurs along the natural plane of cleavage. The chief use of thin slates is for roofing purposes, and they are the most widely used roofing material in this country. Superior qualities are used for writing-slates; and the manufacture of writing-slates is an important industry in North Wales. In thick slabs slates are used for the beds of billiard-tables and for cisterns, and when painted with special enamels and fired, slate forms chimney-pieces made to resemble the different veinings of marble. The hones used for sharpening knives and edge tools are varieties of slate. Much of the supply of hones comes from abroad, Turkey hones, esteemed for edge tools, coming from Asia Minor. Of recent years the chief supplies of hones have come from the United States.

Sponges—Sponges are the elastic skeletons of marine animals, *Porifera*, which inhabit the seas of Europe, America, Africa, and Asia. Sponges grow in seas where the temperatures of summer and winter do not vary much, and in the zone where they are found the best are those where the climate is most nearly uniform and warm throughout the year; those which are on the outer edges of this zone, and which, therefore, are in a climate varying towards the temperate, are coarse and poor in quality. Sponges are most prolific along the shores of islands, and where there are fairly strong ocean currents, which seem to convey to the animals the materials of sustenance. Attempts have been made to improve the culture of sponges by cuttings, but it has not been proved that this increases the number of sponges beyond that produced without cutting. Sponges always grow on hard substances, such as rocks, reefs, and the stems of marine plants. The best are in deep water, and the poorest qualities in shallow water near the shore. The sponges are collected by the use of "harpoons," or thin long poles, with which they are dislodged by divers; or by dredging with a drag net. Sponge divers sometimes work naked, and sometimes in a special dress. If the former, they carry a block of stone to enable them to descend. A diver can remain below for 3½ minutes, but not longer, and usually descends about 20 fathoms. Sponges, when collected, are alive; they die within 24 hours of having been exposed to the air and then the animal remains must be removed so as to leave only the skeleton sponge. The skin is removed, sometimes with a knife, and kneading them, or stamping them out with the feet, gets rid of most of the other animal matter. Then they are washed and dried; they must not be packed before they are dry, or they will spoil. Sponges may be bleached, but the process impaires the durability and purchasers should avoid bleached sponges. There are many varieties of sponges due to different localities. The chief varieties sold are named Turkey and honeycomb--the former being the small-holed, close variety of flat or cap shape, and the latter being the large-holed variety, which is also usually of a paler colour.

TEAK—Teak is the chief wood exported from India and Burma. It is found also in Siam, Java, Cochin China, and in some of the islands of Dutch East India. Teak is the timber of trees of the genus *Tectona* or *Theca*, the Indian teak being *Tectona grandis*. The trees are very large, having trunks 80 ft. to 90 ft. high before the first branch is reached, and a circumference of 20 ft. to 25 ft. The timber is hard, and brown or yellow-brown in colour. Its water-resisting properties make it valuable in shipbuilding. [For strength of teak, see page 1260.]

Tolu—Tolu is the resinous balsam of *Myroxylon toluifera*, a tree that grows in most South American countries. It is bronze yellow in colour and is syrupy when collected, but becomes hard and brittle. It is used in perfumery; and in medicine in its natural state (dose 5 grammes to 15 grammes), and as a syrup, and a tincture. Its chief value in medicine is for coughs and bronchial irritation.

Tortoiseshell — Tortoiseshell is the horny back covering of the *hawk's bill turtle* [see *Turtle*]. The shell from a single animal may weigh up to about 8 lb. For ornamental purposes tortoiseshell has a wide use, and is made into combs and other articles of use and ornament. In its natural state it is very thin, and it is necessary to join together several shells so as to attain thickness. The shells are boiled or are heated in oil, when they become soft, and may then be moulded to any desired form or welded together into intimate union.

Turtles—Turtles are marine animals belonging to the order *Chelonia*. Two of the species are commercially important—the hawk's bill turtle (*Chelone imbricata*), which inhabits tropical seas, and which furnishes tortoise-shell [see *Tortoiseshell*], and the edible or green turtle (*Chelone midas*), which is found throughout the Southern oceans, and particularly near the Bahamas. The green turtle sometimes weights up to 5 cwt. or 6 cwt., and may be as long as 5 ft. Its fat is of a green colour, hence its name. Its use is for the turtle soup, and the consumption is large, especially in London. In the Bahamas, when the turtles land to deposit their eggs, they are simply turned on their backs and are incapable of turning over again. The Chinese catch turtles with a sucking-fish, to the tail of which they attach a string; the fish fastens upon a turtle, and both turtle and fish are drawn into the boat.

VANILLA—Vanilla is the cured pods of *Vanilla planifolia*, a climbing plant native to Mexico, but now grown in Ceylon, Mauritius, and other parts of the globe. Other varieties of plants contribute to the supplies of commercial vanilla, but that mentioned is the chief. The pods are developed only after the flowers have been fertilised, and artificial pollination is practised to increase the yield. The pollen is placed by hand upon the stigma, a small pointed cane being used for the purpose. The pods are cured, and this develops the flavour, the curing process consisting in immersing them into water almost at boiling point, and immediately withdrawing them and putting them into baskets lined with blankets, afterwards drying them in heated rooms. The active principle is vanillin. An artificial vanillin, made from sugar, is one of the recent triumphs of modern chemistry.

WALNUT—The walnut tree (*Juglans regia*) grows extensively in North Europe and Asia. For uses and strength of the timber, see pages 57 and 1260. Great Britain imports the walnuts from Italy, Germany, and France. Before being packed they are dried in a kiln, a process that preserves them but injures their flavour. American walnut, or black walnut (*Juglans nigra*), is valued for its appearance, and is used for furniture, both solid and as veneer.

Whalebone—Whalebone is not bone, but is the substance of the nature of bristles with which the mouths of certain varieties of whales are furnished in order that they may catch and crush the small fish and sea animals on which they feed. Whalebone resembles hardened hairs cemented together, and in its characteristics is more like horn than bone. There are several species of whalebone whales both in the Northern and in the Southern seas. A Greenland whale of full maturity provides about a ton of whalebone. The sides of the upper jaw are the places where the whalebone is found, and each side usually has about 300 blades, which are from 12 ft. to 15 ft. long, being longest in the middle, and 10 in. or 12 in. broad at the base, with a thickness of not quite half an inch. Before being cut up, the blades are cleaned and softened by being boiled for a few hours, and are then, while still hot, planed or shaved by hand, the tool used resembling a spokeshave. After being planed, the whalebone is polished, usually with the edge of a piece of glass or a steel scraper, then with emery powder, and finally with powdered rottenstone. Commercially, the value of whalebone lies in its elasticity, flexibility, and strength. The roots of the blades, where they are thickest are used in the manufacture of walking-stick and umbrella handles, and other purposes. The use of whalebone as a material for the ribs of corsets is practically a thing of the past, as it has been superseded by steel.

THE SELF-EDUCATOR AT A GLANCE

A CONSPECTUS INDEX ARRANGED IN ORDER OF THE GROUPS, BEING A READY GUIDE TO THE WHOLE CONTENTS OF THE SELF-EDUCATOR

All the Articles in the Self-Educator are briefly summarised in the following pages, under the groups, sub-groups, and sections to which they belong and in order of publication. This affords a brief general survey of the branches of knowledge and also gives an easy means of obtaining a general idea of the scope and nature of the artic'es. Sections of the groups are indicated by side-headings in italics. For particular subjects or items of information, reference should be made to the General Index, beginning on page 6900. A list of plates and frontispieces is given on page 6892.

SELF-EDUCATOR GUIDE TO KNOWLEDGE

A COMPREHENSIVE INDEX TO ALL THE SUBJECTS TREATED IN THE SELF-EDUCATOR

This Index is entirely alphabetical and unclassified, so that reference to it is a simple matter. Any item of information in any subject should be looked for as if the Index were an index to that subject alone, French adjectives, for example, under "Adjective," not under "French"; dynamo brushes under "Brushes," not under "Dynamo." This principle has been followed as far as possible, though, of course, general information in regard to the French language or dynamos is indexed under "French" or "Dynamo." For general surveys of the subjects treated in the Self-Educator, see the Group Index, beginning on page 6893. Page references in italics indicate illustrations. Chemical compounds are indexed under their exact names—e.g., Sulphate of Copper under "Copper Sulphate," with a cross reference for the popular name, Blue Vitriol. Owing to exigencies of space, the numerous dictionaries in the Self-Educator have not been separately indexed. They will be found by reference to the particular subjects.

END OF VOLUME VIII.

The Editor's Last Page

SOMETHING of the sadness of parting creeps into this final page of the SELF-EDUCATOR. The EDUCATOR is now complete. In saying this the thought comes that, after all, we live in a human world. We may aim high and plan long, we may mean well and do well, and yet our path, as we look back upon it, may be strewn with the wrecks of our desires and with shattered hopes. As we look back to the beginning from the end, we see that it could all have been better. We can all say that when the end of anything comes. There would be nothing worth having in experience if we could not.

I am not going to proclaim the faults of the SELF-EDUCATOR from the editor's desk. They are seen there, perhaps, as they can be seen from no other point of view. It is enough for an editor to say that he tried to be perfect and could not; it is all that an editor can hope that his mistakes are not too many for human readers to forgive.

It is pleasant that with all the regrets which retrospect brings there comes a grateful sense of satisfaction. I have not lived long, but I have come to know that nothing in the world is so grateful to a man as success. I did not mean to write "success," but let us be honest and not be afraid of a word. Success is not everything. I would rather have experienced some failures, with all their bitterness and tragedy, than have reaped some of the successes that flaunt themselves blatantly before the world. But we need not be ashamed of success in well-doing, and there is too much false righteousness preached against those who urge young men to succeed. It is not the wise man who wants to fail, and if our life is set in the right path, if our hands are clean and our work is good, let us never for one moment feel that we ought to be ashamed to want success.

And the EDUCATOR has succeeded. There was room for such a book, and it must be better for us, better for our work, better for our lives, better for England, that there should be a vast thinking public with the EDUCATOR on its bookshelves.

It would take the whole of this number to say "Thank you!" to all to whom thanks are due. If, as this last page goes to the printers, I could remember all those with whom it has been a pleasure to come into touch, there would not be room, if I could find the words, to say all that I would say.

Such a publication reaches into a thousand fields. There comes to mind a letter from a lonely boy on the Canadian prairie, who had read of the SELF-EDUCATOR, and wondered how he could get it. There comes to mind, too, the Egyptian boy in Cairo whose two sets of the EDUCATOR have given us such trouble as can only be balanced, let us hope, by the pleasure they have given him. All over the world in the future travellers will come across this work.

There must also be thanked a vast number of correspondents who have been unwearying in their desire for the success of this work, the thousands of readers who have made its success possible, the schoolmasters who have commended it to their schools, those who have asked for an extra volume or suggested extension in other ways that were not possible without the approval of all readers. It is right, also, that it should be known how loyal and helpful the booksellers and newsagents have been. The contributors, the real makers of the EDUCATOR, can never be better rewarded than by the striking public appreciation of their work; but it is due to them to say that, with one or two exceptions, they have proved themselves highly capable, interesting, and the soul of courtesy and forbearance.

One other note of thanks is due. Behind every great work is an army of unknown workers. The editor's name is blazed abroad, but a thousand names remain unknown of those without whose aid an editor's work would never be done. The production of the EDUCATOR has been exceptionally difficult as a result of the effort to keep the work up-to-date instead of allowing it to be produced, as most encyclopædias are, so that it is out of date on its completion. To authors, editors, artists, photographers, printers, newsagents, and a host of other workers the production has for this reason been unusually trying, and especially has it been a strain upon the immediate editorial staff. To my friend and colleague, Mr. J. A. Hammerton, whose short introduction to English literature is one of the essential values of the EDUCATOR, and to all those other members of the staff whose loyalty and hard work have helped to make a burden light, the indebtedness of the SELF-EDUCATOR should be acknowledged.

To them, and to all whom it may concern, I give now that deep and grateful feeling of which our language has but one expression—Thank you!

ARTHUR MEE

THE WORLD'S GREAT MEN

Abbas I., the Great
b. 1557. d. 1628

A man who, in spite of many crimes, was one of the greatest of Persia's sovereigns. Successfully rebelling against his father, he put to death one or more of his brothers, and ascended the throne in 1587. Suppressing lawless soldiery and a feudal nobility which menaced the throne, he embarked upon a brilliant career of conquest, and was assisted by a British fleet to wrest Ormuz from the Portuguese. At his death the Persian Empire had been extended from the Tigris to the Indus. Terrible cruelties were practised at his behest, but his system of government was enlightened and praiseworthy.

Abel, Sir Frederick August
b. London, July 17 1826 d. London, September 6 1902

Among the first students of the Royal College of Chemistry, he became, at twenty-seven, chemist to the War Office and chemical referee to the Government. He divested the preparation of gun-cotton of danger, and paved the way for smokeless powder, of which cordite invented by himself and Sir J. Dewar was adopted by the Government. His petroleum investigations determined the standard for flash-point; while in electricity and steel manufacture he won a special standing. He was President of the British Association in 1890.

Addison, Joseph
b. Milston, Wilts, May 1, 1672 d. Kensington June 17 1719

"Whoever wishes to attain an English style, familiar but not coarse and elegant but not ostentatious, must give his days and nights to the volumes of Addison." Dr. Johnson's estimate of our foremost light essayist still holds good. Obtaining through his patron, the Earl of Halifax, a pension of £300, he spent four years on the Continent, after which his poem, "The Campaign," celebrating the victory of Blenheim, secured him an Excise Commissionership. While secretary to the Lord Lieutenant of Ireland he formed a close friendship with Swift. The "Tatler," started by his friend Steele, had Addison among its regular contributors; as had the "Spectator," founded two years later. A quarrel with Pope led to his being satirised by the latter as Atticus. Appointed a Commissioner for Trade and the Colonies, he was embroiled in disagreement with Steele. Three years before his death he married Charlotte Countess of Warwick. His fame rests not upon his poetic or dramatic writings, but upon the essays which caused him, while recognised as a contributor to the gaiety of the nation, to be hailed as "Guilt's chief foe."

Adrian IV. See Breakspear, Nicholas

Æschylus
b. Eleusis, Athens, 525 B.C. d. Gela, Sicily, 456 B.C.

The father of Greek drama was born of noble family, and before giving his mind wholly to poetry, shared with his brothers the perils of war against the Persians. His successful first appearance in the dramatic contest was in 484, when he won the prize with the trilogy of which the "Persians" formed part. Afterwards he enjoyed a series of thirteen victories, interrupted by the advent of Sophocles. This defeat, coupled with indignation at the doubts cast upon his piety, caused him to retire to Sicily, where, after other poetic triumphs, he died. Only seven of the sixty plays ascribed to him are extant, but these place him on a pinnacle of unapproachable height.

Æsop
b. Phrygia, Asia Minor, 620 B.C. d. 561 B.C.

For neither date can there be any pretence at [illegible]. Very little is known of the immortal fabulist beyond that he was born a slave in Phrygia, and sold eventually to Jadmon the Samian, by whom he was freed. He visited the Court of Crœsus, by whom he was sent on various missions, which enabled him to travel in Greece and Asia Minor, inculcating morals by his fables. He is said to have met his death through being thrown over a precipice by the priests of Delphi.

Agassiz, Jean Louis Rodolphe
b. Motiers, Switzerland, May 28, 1807 d. Cambridge, England, Dec 14, 1873

An indefatigable naturalist, whose writings, when he was twenty-six, won the praise of Cuvier. His work on the glacial phenomena of the Alps, on fossil fishes in Europe and the American Continent, his lectures at various seats of learning, and his gifts of priceless collections, did much to advance the science to which he devoted his life.

Agha Muhammad Khan Kajar
b. 1740 d. Shishah, Persia, 1797

After Persia had been for many years torn by civil war, he acquired the sovereignty in 1794, and founded the existing dynasty. He promoted commerce and reforms, but was one of the cruellest monsters that ever wore a crown. Mutilated himself early in life, he treated his enemies with frightful barbarity. Once, after ordering a general massacre of women and children, he had 70,000 eyes of his subjects put out. He was assassinated in 1797.

Agricola, Cnæus Julius
b. Fréjus, France, 37 A.D. d. August 23, 93 A.D.

He thoroughly conquered Britain and a great part of Scotland; he gave the land wise laws, and induced the Britons to embrace Roman manners, and to have their children taught the Latin tongue. Also, he enriched the land with many noble buildings. He was the first to discover that Britain is an island. Recalled and humiliated by the jealous Domitian, he died at the age of fifty-five. Tacitus was his son in law.

Ahmed Shah
b. 1724 d. 1773

The first sovereign of Afghanistan was in his youth in the service of Nadir Shah. Upon the assassination of the latter he retired to Kandahar, and persuaded the native tribes to assert their independence and make him king. He proved a talented military leader. The Koh i-Nur was one of his many rich possessions.

Aird, Sir John, Bart., M.P.
b. London December 3 1833

The son of a working man, Sir John Aird has raised himself by industry, integrity, and genius to the rank of one of the foremost contracting engineers in the world. His greatest work is the Assouan dam, the reservoir in connection with which holds 80,000,000,000 gallons of water.

Alaric I.
b. 376 d. Cosenza, Calabria, Italy, 410

Chief, afterwards King, of the Visigoths, Alaric, though the leader of barbarians, was himself an Arian Christian. Although the great general Stilicho defeated him, he proved the foremost military commander of his age. He pillaged Athens; thrice besieged, and once, for six days, sacked Rome; deposed its Emperor, and set up another. Many barbarities were practised by his troops, in spite of his humane intentions; but he caused women to be spared and religious buildings to be preserved. At his death the river Busento was diverted from its course that he, with all his treasure, might be buried in its bed. The work completed, those who had carried it out were put to death, that the secret might be maintained inviolate.

Alcibiades
b. Athens, 450 B.C. d. Phrygia, Asia Minor, 404 B.C.

This famous general and statesman came early under the influence of Socrates, who saved his life in battle, to be himself rescued by Alcibiades at the battle of Delium. Brave and talented, Alcibiades lacked mental ballast. Mutilation of votive statuary in Athens caused him to flee into Lacedæmon, and thence to Persia, to be recalled in triumph to Athens. His military expeditions culminating finally in disaster, he passed into Phrygia, where, by Spartan orders, he was assassinated—his house being fired, and himself struck dead by darts as he emerged

Alexander the Great
b. Pella, Macedonia, 356 B.C. d. Babylon, [illegible]

The son of Philip of Macedon, Alexander, educated by Aristotle, was regent of his father's kingdom at sixteen, at eighteen won his first battle, and two years later became king. Having subdued the Greeks and consolidated his power in Europe, he, in 334 B.C., with 30,000 foot and 5,000 horse, crossed into Asia, never to return. Defeating the Persians, he took Tyre, conquered Syria and Egypt, and founded Alexandria; defeated Darius, conquered Parthia, Media, and Bactria, invaded India, and over-ran Asia; then returned to Babylon, where he died from the effects of excessive drinking. Many appalling crimes tarnish his fame, but his influence for good was felt for centuries; for he caused to be diffused far and wide Greek art, science and philosophy, and gave an impetus to learning where barbarism in its worst forms had reigned. He left no successor, and at his death his vast empire was divided among his generals.

Alexander II. of Russia
b. April 29, 1818. d. St. Petersburg, March 13, 1881.

The son of Nicholas I., who upon his death-bed exhorted him to free the serfs, Alexander nobly carried out that mandate, and six years after his accession, emancipated 23,000,000 of his subjects. Russian territory was widely extended during his reign, which ended in a great tragedy. The Nihilists, who had thrice attempted his life, assassinated him on the very day upon which he was to have signed a Constitution for Russia. His eldest daughter married Queen Victoria's second son, the Duke of Edinburgh.

Alfieri, Vittorio
b. Asti, Italy, January 17, 1749 d. Florence, October 8, 1803

The son of a noble house of Piedmont, Count Alfieri led for some years a life of indolence and luxury, but in middle age made himself master of Latin and Greek. He wrote many tragedies and comedies, some of which still keep the stage. Their effect was to popularise a purer Italian literature.

Alfonso X., the Wise
b. 1226. d. 1284

Succeeding his father as King of Leon and Castile, he won victories over the Moors, and united Murcia to Castile. With him Castilian literature had its birth. He caused the first general history of Spain to be written, and the Old Testament to be for the first time translated into Castilian. His life was embittered by the rebellion of his sons, of whom Sancho eventually deposed him.

Alfred the Great
b. Wantage, Berkshire, 849 d. October 27, 901.

The wisest, best, and greatest King that ever reigned in England was the fifth and youngest son of Ethelwulf. His reign was one long struggle with the Danes, who, upon his accession, in 871, were masters of practically the whole of England north of the Thames. He waged war with varying fortune until finally he made himself King of all England. Such is the veneration in which his memory is held that it has been customary to ascribe to Alfred every privilege which Englishmen enjoy. What he did was to codify the best laws enacted by his predecessors, to found a Navy, encourage learning and industry, and, for the first time, to consolidate England into a united monarchy. His will, a notable document, is preserved, but it is not known where, or from what cause, he died.

Alleyn, Edward
b. London, September 1, 1566 d. London, November 1626

An actor famous as a contemporary and neighbour in London of Shakespeare, in whose plays he frequently performed. Successful theatrical speculation, reinforced by money gained by marriage, enabled him to buy for £10,000 (worth now five times that sum) the 1,300 acres with which he endowed his College of God's Gift at Dulwich. The value of the property, which is constantly increasing, is now upwards of two millions sterling.

Amadeus VIII.
b. Chambery, France 1383 d. Geneva, 1451

He caused Savoy to be erected into a duchy, then ruled Piedmont, but relinquished temporal cares for a hermitage, whence he emerged to be Pope, as Felix V. He filled the Papal chair for ten years, resigning in favour of Nicholas V.

Anaxagoras
b. Clazomenæ, Asia Minor, 500 B.C. d. Lampsacus, Asia Minor, 428 B.C.

The philosopher who paved the way for the atomic theory, had the courage to trace eclipses to natural laws, to divest the sun of its halo of deity, and correctly to analyse the origin of meteoric stones. His views conflicting with the superstitions of the age, he was driven forth to die in exile.

Andersen, Hans Christian
b. Odense, Denmark, April 2, 1805 d. Copenhagen, August 4, 1875

The divinity of the nurseries throughout the civilised world was the son of a poor shoemaker, and early in life had to work in a factory. The beauty of his voice induced him to attempt the stage, but for this he was declared too uncultured, and it was not until his early poems had attracted attention that he was enabled by sympathetic admirers to equip himself at a good school. His fairy stories are by this time classics.

Anderson, Alexander
b. Kirkconnel, Scotland, April 30, 1845

Bred to the work of the colliery, Mr. Anderson managed, while working on the pit-brow, to master French, Italian, and German, and to read the great poets in their own languages. Now the pit knows him no more; he has been appointed chief librarian of Edinburgh University. Of his many charming poems there is one—"Cuddle Doon"—of which Sir George Douglas says, "Scotland has made this as much her own as she has made Burns's songs." The poem is, indeed, a gem of music, humour, and tenderness.

Angelico, Fra
b. Vecchio, Italy, 1387. d. Rome, March, 1455

Fra Angelico is the name by which is best known Giovanni or Guidolino da Pietro, the great painter of religious subjects. He is specially famed for the spirituality and mystical charm of his saints and angels. Best examples of his work are at the Vatican, the Louvre, in the Uffizi, and at Orvieto.

Angelo, Michael. See Michaelangelo

Antony, Mark
b. 83 B.C. d. Alexandria, August, 30 B.C.

Related to Cæsar, and one of his closest adherents, Marcus Antonius induced the latter to make his (Antony's) expulsion from Rome the pretext for civil war, and himself led the left wing of Cæsar's army. At the death of Cæsar he played the rôle in which Shakespeare immortalised him. Forming, with Octavian and Lepidus, the second Triumvirate, he defeated Brutus and Cassius;

then summoned Cleopatra, Queen of Egypt, to meet him to settle an outstanding dispute. Captivated by her beauty and address, he followed her into Egypt. Called again to Rome, he was eventually defeated at Actium by Octavian, and fled to Egypt, where, deserted and alone, and deceived by a report of Cleopatra's death, he destroyed himself.

Apelles

b. Colophon, Asia Minor, 340 B.C. d. Cos, Asia Minor, 304 B.C.

Alexander the Great permitted only one man to make his statue, and only one man to paint his portrait. The painter was Apelles, the greatest artist of antiquity. He was most famed for his portraits, but his subject pictures were brilliant. He fell in love with Campaspe, a mistress of Alexander, who, it is told, surrendered her to the painter. From Campaspe Apelles drew his finest picture, "Venus rising from the Sea." Apelles had a varnish, the secret of which has been lost, whereby he added mellowness and beauty of tone to his work. He followed Alexander into Asia as far as Ephesus.

Aquila, Ponticus

b. Sinope, Asia Minor, 100 A.D.

Dates cannot with certainty be stated, but Aquila flourished about 130 A.D. He was skilled as a mathematician and architect, and was employed by his kinsman, the Emperor Hadrian, to assist in rebuilding Jerusalem. He gave the Greeks their first translation of the Old Testament, and was himself successively pagan, Christian, Jew.

Aquinas, Thomas

b. Calabria, Italy, 1225. d. Terracina, Italy, 1274.

Descended from the Counts of Aquino, Aquinas was born at his father's castle, Rocca-Secca, in which, upon his determining to enter the Dominican order against the parental wishes, he was imprisoned for two years. Escaping, he made his way to Albert Magnus, under whom he studied, until, long called "the dumb ox," he verified the saying of his master that "the voice of the ox shall one day fill the world." As a teacher he at once won fame. Having little Greek, and less Hebrew, he yet commanded the attention of the civilised world with his writings and with expositions of the Scriptures. Called now "the Angel of the Schools" and "the Eagle of Divines," he refused all Church preferments, remaining to the end simply the great theological scholar. At his death posthumous honours were heaped upon him. His "Summa Theologiæ" remains to-day substantially the standard authority of the Roman Catholic Church.

Archelaus

b. Athens, B.C., 480 (?).

The Ionic philosopher, scholar of Anaxagoras, who first demonstrated that the earth is round. This truth he deduced from observing that the sun rose and set at different times upon different parts of the earth. His fame was at its height in 450 B.C.

Archimedes

b. Syracuse, Sicily, 287 B.C. d. Syracuse, 212 B.C.

The "greatest mathematician and most inventive genius of antiquity"; first to establish the idea of specific gravity; perhaps, too, of the lever, in relation to which he uttered the well-known phrase, "Had I but a fulcrum whereon to rest, I could move the earth." The endless screw, the spiral pump for water, and innumerable engines of war which he was persuaded by his king to provide to withstand the assaults of the Romans—these, with great cranes, "burning mirrors," various hydraulic and compressed-air machines, were among his inventions. He preferred theory to practice, and despised his inventions. When the Romans at last broke through the defences of Syracuse, they found Archimedes bending over his diagrams drawn in the sand, and there killed him.

Ariosto, Ludovico

b. Reggio, Italy, September 8, 1474. d. Ferrara, Italy, June 6, 1533.

Educated as lawyer, soldier, scholar, Ariosto had with distinction discharged military duties, subjected a rebellious province, ruled as governor for three years, and conducted diplomatic missions before he devoted himself to writing. His works, which have long become classics, consist of satires, comedies, sonnets, songs, and lesser poems. But his great achievement is the grand, heroic poem, "Orlando Furioso," the completion of which occupied him sixteen years. It takes up Boiardo's unfinished "Orlando Innamorato," and with art which seems artless improvisation thrills and enchants by almost every page.

Aristarchus

b. Samos, Asia Minor, 280 B.C. d. Samos, 264 B.C.

A Greek astronomer, who, by demonstrating that the earth moves round the sun, anticipated the discovery of Copernicus. He measured the distances of the sun and moon from the earth; but, while he was geometrically correct, his lack of adequate instruments rendered his results inaccurate.

Aristides, The Just

b. Athens (?). d. Athens, 468 B.C.

The man whom Athens surnamed The Just was one of the ten generals at the Battle of Marathon, and, by inducing the others to surrender supreme control to Miltiades, enabled that general to win the day. Great in battle, and of noble character, he made Athens the ruling state in a maritime confederacy, and enabled every citizen, no matter what his rank or riches, to be eligible for the archonship. He died in honest poverty, and was buried by the state, which awarded his descendants pensions.

Aristophanes

b. Athens, 444 B.C. d. 380 B.C.

The greatest of Greek comic poets. The licence of the Athenian stage enabled him to expose abuses and evils inimical to the commonweal. Eleven plays—only a fifth of the number he wrote—are extant. Some are gross and coarse, reflecting not so much the mind of the man as his age. His work is characterised by infinite wit and fancy, and here and there power and beauty. "The Acharnians," "The Knights," "The Clouds," "The Wasps"—these, the four best known, alone suffice to secure his standing with the immortals.

Aristotle

b. Stageira, Macedonia, 384 B.C. d. Chalcis, Greece, 322 B.C.

One of the greatest philosophers of antiquity, Aristotle became, at the age of seventeen, the pupil of Plato, and for three years had for his own pupil Alexander the Great, who quitted the side of his master to go forth upon his career of conquest. Aristotle then opened his famous school in Athens, which he called the Lyceum, from its proximity to the temple of Apollo Lyceius. Here he treated of every subject which came within the range of ancient thought, and was rightly viewed, even down to Dante's day, as "the master of those that know." His influence and teachings remained the barrier between later eras and barbarism. His piety being impugned, remembering the fate of Socrates, he fled to Chalcis, in Eubœa, where he died, saying, as he left Athens, "I do not wish to see the Athenians sin twice against philosophy."

Arkwright, Sir Richard

b. Preston, Lancs, Dec. 23, 1732. d. Cromford, Derbyshire, Aug. 3, 1792.

The youngest of thirteen children, Arkwright began life as a dealer in human hair, which he dyed and sold for wigs. His education was so meagre that not until he was fifty had he time to master grammar and orthography. His invention of the spinning-machine revolutionised the cotton industry. The machine was made when he was so poor as to be in rags. He was thirty-six

when he set up his first machine in Nottingham, and had a hard battle to fight. A mob destroyed his factory at Chorley; masters and men were hostile to the new invention; protracted litigation greatly vexed him. In the end his triumph was pronounced. He originated factory labour; he created an industry representing untold wealth to his country. Not over-scrupulous in his dealings with other inventors, he was still a good master, and himself set an example of industry by working sixteen hours a day.

Armstrong, Lord

b. Newcastle-on-Tyne, Nov. 26, 1810. d. Rothbury, N'berland, Dec. 27, 1900.

The solicitor who revolutionised warfare was practising law while concerned with his first inventions. A colliery accident led to his investigating the generation of electricity from steam, and from this he worked on to the hydraulic crane, and all the hydraulic machinery for which his great works first became famous. At forty-nine he made his first big gun, and from that moment the history of heavy ordnance was changed. At first all his productions were for the British Government, but afterwards his business was extended to the Continent, and for field service and battleships his guns won world-wide reputation.

Arnold, Matthew

b. Laleham, Middlesex, December 24, 1822. d. Liverpool, April 15, 1888.

Poet, critic, educationist, author of the daintiest prose which conveyed hard-hitting truths, and of poetry which is pure music, Arnold has left a mark upon English literature and public life which will not soon be obliterated.

Arnold, Thomas

b. East Cowes, Isle of Wight, June 13, 1795. d. Rugby, June 12, 1842.

Father of the foregoing, Dr. Arnold, though a scholarly writer with a record of noble works, is best remembered for having revolutionised public school education in England during the fourteen years he was headmaster of Rugby.

Arrol, Sir William, Kt.

b. Houston, Renfrewshire, 1839.

The son of poor parents, Sir William Arrol began life as a cotton-piecer, was apprenticed at fourteen to a blacksmith, and with a capital of £85 began business on his own account. His energy and initiative broke down all obstacles to success, and at thirty he was building the new Tay Bridge, at a cost of three-quarters of a million. The Forth Bridge, and later the Tower Bridge, followed, and innumerable other great schemes. For these enterprises he had to invent practically all his own tools, and by so doing created a new and remunerative industry.

Ashmole, Elias

b. Lichfield, Staffordshire, May, 1617. d. London, May 18, 1692.

A man who, though he hung spiders about his neck for ague, and dabbled in alchemy, will, as his epitaph says, be remembered as long as his museum endures. This he got for the most part from his friend John Tradescant. He gave all, with the residue of the library which he had been thirty years collecting, to Oxford University. Fire had greatly damaged his library, but the Ashmolean museum is still famous for its manuscripts.

Athanasius, St.

b. Alexandria, Egypt. 29 A.D. d. Alexandria. 373 A.D.

The greatest of the Greek Fathers, of whom Gibbon says, "His immortal name will never be separated from the Catholic doctrine of the Trinity, to whose defence he consecrated every moment and every faculty of his being." He was the great champion of the Church against Paganism and Arian heresy, and spent twenty years of his life in exile—six in the desert, a hunted fugitive. Athanasius, who introduced monasticism into Western Europe, is not the author of the Athanasian Creed, of which nothing was heard until long after his time.

Attila

b. 406 A.D. d. Pannonia, Europe, 453 A.D.

"The Scourge of God," descended from the ancient Huns who dwelt on the confines of China. Putting his brother Bleda to death, he became master of the then vast kingdoms of Germany and Scythia, his dominions extending from the Rhine to the frontiers of China. He invaded Rome, and compelled Theodosius to pay tribute. This Marcian, the latter's successor, refused to continue, and in a great battle Attila was defeated. He again invaded Italy, and fugitives, flying before him, founded what was to become the famous Venetian Republic. Attila, whose boast was that "grass never grows again where my horse has once trodden," left an empire which his sons, by civil wars, rapidly destroyed.

Augustine, St.

b. Tagaste, N. Africa, Nov. 12, 354 A.D. d. Hippo, N. Africa, Aug. 28, 430 A.D.

The father of Augustine was a Pagan until late in life, and Augustine himself lived a life of licentiousness upon first going to Carthage. Cicero and Plato called him to nobler aims, and it was from the study of philosophy that he turned to Christianity, being baptised when thirty-four. His immortal autobiographical "Confessions" were written when he was forty-four. To heresy he proved a redoubtable foe, and for centuries after his writings ruled the Christian Church. He died while the Vandals were besieging Hippo, of which he was at the time bishop.

Augustus, Cæsar

b. 63 B.C. d. Nola, Italy, 14 A.D.

The man who found Rome built of brick, and left it built of marble, was the grand-nephew of Julius Cæsar, to whose will, after a struggle with Mark Antony, he gave effect. He parted the Roman world with Antony and Lepidus, who took – the former Gaul, the latter Spain; while Augustus himself had Africa, Sardinia, and Sicily. By his victory at Actium over the forces of Cleopatra, after which she and Antony committed suicide, he became the enlightened and noble master of the Roman world. His name, really Caius Julius Cæsar Octavianus, was changed to Augustus, meaning sacred or venerable, and it exists to-day in the name of our month of August, which formerly was Sextilis, then the sixth month of the Roman year.

Austen, Jane

b. Steventon, Hampshire, Dec. 16, 1775. d. Winchester, July 18, 1817

The heroine of an enthusiastic eulogy by Macaulay was a daughter of the rectory, studied French and Italian, and was conversant with Richardson, Johnson, Crabbe, Cowper, and, at a later period, with Scott. She introduced the novel of domestic life. Four of her best-known novels were published anonymously during her life; the others were not given to the world until the year following her death. "Sense and Sensibility" and "Pride and Prejudice" were written before she was twenty-two.

Bach, John Sebastian

b. Eisenach, Germany, March 21, 1685. d. Leipzig, July 28, 1750

A member of a family of musicians, Bach was entirely self-taught. He never had instruction in instrumentation, nor in the theory of music. He created his own style. "Every room in which Bach is sung is transformed into a church," said Mendelssohn. Blindness fell upon him in his latter days, and the operation attempted for his relief brought about his death.

Bacon, Francis

b. London, January 22, 1561. d London, April 9, 1626.

"The wisest, brightest, meanest of mankind," as Pope termed him, died Lord Verulam and Viscount St. Albans. He never was Lord Bacon, the name by which he is commonly called. His career as a public man was marred by servility and treachery. He fawned upon the powerful, to

turn without mercy upon them—notably, in the case of the Earl of Exeter—when his ends had been served. Successively filling all the offices of State leading to the Lord Chancellorship, he fell from the latter office, convicted of the grossest corruption, was sentenced to imprisonment in the Tower, fined £40,000, and banished the Court and Parliament. The sentence was remitted, but he continued in retirement. His literary labours entitle him to be styled the "father of English learning." While he was ignorant of discoveries of his contemporaries, and cherished many superstitions, he gave an impetus to English learning such as no other man had done.

Bacon, Roger
b. Ilchester, Somerset, 1214. d. Oxford, 1294.

The "wonderful doctor," as he was called, became a monk of the Franciscan order, which prevented his publishing his writings. He dabbled in alchemy, but made notable discoveries, gunpowder and the magnifying-glass among them. He is famous as being the pioneer of modern scientific inquiry. Persecuted and hindered to an unparalleled degree, he yet contrived to leave a striking record of work accomplished.

Baker, Sir Samuel
b. London, June 8, 1821. d. Newton Abbot, Devon, December 30, 1893.

A daring traveller, who, with his wife, essayed the exploration of the Nile sources, and, in company with Speke and Grant, discovered the great lake to which he gave the name Albert Nyanza. He helped to suppress slavery in Egypt, explored Cyprus, extended his travels east and west, and wrote one or two valuable books.

Balfe, Michael William
b. Dublin, May 15, 1808. d. Rowley Abbey, Herts, October 20, 1870.

An Irish composer, whose memory is dear to multitudes who have been charmed with his melodious operas and other compositions.

Baliol, John de
b. Barnard Castle, Durham. d. 1269

One of the wealthiest barons of his time, he founded Balliol College, Oxford. His third son, John de Baliol (1249-1315), became King of Scotland, but was taken prisoner by Edward. His son Edward recovered the crown after a bloody battle, in which the Regent Mar was slain, but died in 1367. With him the line of Baliol ended.

Balzac, Honoré de
b. Tours, France, May 20, 1799. d. Paris, August 18 1850.

An indefatigable French author, who in twenty years wrote eighty-five novels, several of them masterpieces. His "Comédie Humaine," in which every phase of life and character was to be treated, proved too vast an undertaking, but in it is some of his finest work.

Baring, Sir Francis
b. Larkbear, Devonshire, 1740. d. Lee, Kent, 1810.

The son of an immigrant German, who, along with his brother John, founded the financial house of Baring Bros. Lord Cromer and Lord Northbrook descend from the same stock.

Bayard, Pierre du Terrail
b. Grenoble, France, 1476. d. Italy, 1524.

The last of the great heroes of chivalry, he was, at the age of eighteen, the most accomplished knight of his time. His feats in war and council were equally notable. He was for thirty years regarded throughout Europe as the mirror of chivalry, and his name still serves as a synonym for noble, unselfish, and heroic deeds.

Becket, Thomas
b. London, 1118. d. Canterbury, December 29, 1170.

Of Norman parentage, Becket showed extraordinary ability as a young man, and, securing the patronage of the Archbishop of Canterbury, was employed to win the Papal recognition of the Plantagenet dynasty on the English throne. From 1155 Becket was Chancellor—ostentatious, unscrupulous, and worldly. Then, in 1162, the Archbishopric of Canterbury was forced upon him by Henry II. The office wrought a miracle in his life. The worldling gave place to the stern ascetic and great champion of the Church. He asserted her rights, and boldly denied the Royal prerogative, but was forced to fly to France, and remain in exile for six out of his eight years' primacy. The struggle ended in his assassination at the altar of Canterbury Cathedral by knights acting upon the exclamation of the King: "Of the cowards that eat my bread, will none rid me of this turbulent priest?"

Bede, The Venerable
b. Monkwearmouth, Durham, 673. d. Jarrow, Durham, 735

The father of English history was educated at a monastery between Monkwearmouth and Jarrow. There he spent all his days diligently compiling his history, his scientific and theological treatises, and teaching and expounding with such distinction as to make Northumbria the literary centre of Western Europe.

Beethoven, Ludwig Von
b. Bonn, Germany, December 16, 1770. d. Vienna, March 26, 1827.

Beethoven, like Bach, was one of a musical family, and at fifteen was Court assistant-organist, having already appeared as a juvenile pianist. By the time he had attained his twenty-third year he was noted as the most brilliant extempore player of his day. He now went to Vienna to study, and there remained for the rest of his life. His compositions comprise all forms of music—vocal and instrumental from the sonata to the symphony, from the simple song to the opera and oratorio. Upon his works the modern school of instrumental music has been founded.

Bell, Sir Charles
b. Edinburgh, November, 1774. d. Worcester, April 28, 1842.

He made the greatest discovery in physiology from the time of Harvey to his own day—the distinction between the sensory and motor nerves. He held many high positions in his profession, and took charge of the wounded after the battles of Corunna and Waterloo.

Bell, Alexander Graham
b. Edinburgh, March 3, 1847.

The inventor of the telephone is the son of a famous father, Alexander Melville Bell, author of the system of "Visible Speech." It was while teaching this system that Bell the younger invented the telephone. He deposited his drawing and specifications the same day on which Mr. Elisha Gray filed particulars of his telephone. Edison's differed somewhat from both. Mr. Bell has since then invented the photophone, which transmits sound by variations in a beam of light; the graphophone, and similar instruments.

Bell, Henry
b. Torphichen, Linlithgow, 1767. d. Helensburgh, Dumbarton, Nov. 14, 1830.

The father of European steam navigation was first a wheelwright, then a ship modeller, and next worked under Rennie, the famous engineer. He helped Fulton to make his steamboat; and himself, after many years' patient toil, produced his Comet, a boat of twenty-five tons, propelled by an engine of 3 h.-p. at a speed of seven miles an hour.

Belzoni, Giovanni Battista
b. Padua, Italy, 1778. d. Benin, W. Africa, December 3, 1823.

First a monk, he was driven, by the invasion of Rome by the French, to England, where he earned a livelihood in the streets as a "strong man." Starting his career proper, he explored Egypt, and invented a hydraulic machine for raising the waters of the Nile. He removed and sent to England the colossal statue of "Young Memnon," and was the first to enter the second great pyramid of Gizeh. He was the father of modern Egyptian research.

Bentham, Jeremy
b. London, February 15, 1748. d. London, June 6, 1832.

The son of an attorney, he devoted his life to ethics and jurisprudence, and, in the words of Mill, found the philosophy of law a chaos, and left it a science. He advocated universal suffrage, annual Parliaments, the ballot, and payment of members. To many of his ideals effect has already been given by Parliament. His skeleton, dressed in the clothes he wore, is preserved at University College, London.

Becquerel, Alexander Edmond
b. Paris, March 24, 1820. d. Paris, May 13, 1891.

The son of Antoine Cæsar Becquerel, who was noted as a physicist, he made important investigations in relation to light, and discovered the rays to which his name is given.

Bergmann, Torbern Olof
b. Sweden, 1735. d. Upsala, Sweden, 1784.

Although a victim of poor health, he showed extraordinary assiduity in problems in botany, geology, and mineralogy. His theory of elective or chemical affinities has had a great influence on the later developments of chemistry.

Berlioz, Hector
b. Isère, France, December 11, 1803. d. Paris, March 8, 1869.

A composer whose genius was often akin to madness, he had for long to depend for a livehood upon musical criticism instead of musical composition. In the end his triumph was complete, his "Faust," "Romeo and Juliet," "Beatrice and Benedict," "Messe des Morts," and "Te Deum" sufficing to make for him a reputation which time enhances.

Berthelot, Pierre Eugène Marcellin
b. Paris, October 29, 1827.

The father of synthetic chemistry, the chemistry which builds up new forms, fled from a priestly seminary to devote himself to science. Other scientists had analysed and broken up matter; he put together the fragments, invented explosives and chemical and commercial products innumerable. To-day the school which has grown up in his train enumerates and defines fifty thousand distinct compounds. He has been Minister for Education and for Foreign Affairs of France.

Bertillon, Alphonse
b. Paris, 1853

A French police officer, who re-equipped the detective forces of the world by inventing a means of identifying criminals by measurements.

Bessemer, Sir Henry
b. Charlton, Herefordshire, January 19, 1813. d. London, March 15, 1898.

Many inventions, some of which never yielded him any profit, stand to the credit of Bessemer, but his process for the cheapening of steel is his chief claim to fame. He discovered that by forcing a blast of air through the molten metal he could decarbonise it, and convert cast iron into steel. His discovery did not at first yield the desired results, and he was discredited. Years of disappointment followed, but he persevered until his invention was finally perfected, and, by producing steel from his own works at £20 a ton less than the trade generally, rehabilitated himself. He made a vast fortune, and revolutionised the steel industry of the entire world.

Bichat, Marie François Xavier
b. Thoirette, France, 1771. d. Paris, July 22, 1802.

A happy accident brought his abilities to the notice of Desault, who forthwith adopted him as his son. Profiting by the knowledge thus early placed at his disposal, Bichat became the greatest anatomist and physiologist of his age. He was the first to reduce the complex structure of the organs to their elements, and to simplify the whole science.

Bismarck, Prince Otto Edouard Leopold
b. Schönhausen, Germany, April 1, 1815. d. Friedrichsruh, July 30, 1898.

Destined to complete the work of Frederick the Great, Bismarck was first opposed to all popular reform, and, though he was afterwards to give universal suffrage, he voted against a constitution for Prussia. Experience as Prussian representative at the Frankfort Diet, and as Ambassador to Russia and France, modified his views, and it was a more liberal Bismarck who was called to the assistance of the despairing King of Prussia. He employed Austria to help in wresting Schleswig-Holstein from Denmark, then turned on Austria and crushed her, making Prussia supreme in Germany. France had next to be faced, and a four years' preparation culminated in Bismarck's falsifying a telegram to misrepresent a meeting between the King and French Ambassador. The Franco-Prussian War followed. Here, again, German arms were triumphant; and while the Second Empire was being crushed, Bismarck confederated the German States into the German Empire, with the King of Prussia as German Emperor. Loaded with honours and rewards, Bismarck retained office until 1890, when he was dismissed by William II.

Black, Adam
b. Edinburgh, February 20, 1784. d. Edinburgh, January 24, 1874.

A worthy publisher, who originated the "Encyclopædia Britannica," and became proprietor of the "Edinburgh Review" and of the copyright of Scott's novels.

Black, Joseph
b. Bordeaux, France, 1728. d. Edinburgh, November 26, 1799.

The founder of modern chemistry was the son of a wine-merchant. He exploded the theory that the causticity of lime and the alkalis is due to their absorption of the so-called phlogiston, and traced it to carbonic acid. His discovery as to latent heat was of still greater importance to subsequent investigators.

Blake, Robert, Admiral
b. Bridgwater, Somerset, August, 1598 d. Plymouth, August, 1657.

Was a member of the Long Parliament, and in the Civil War gave the turning-point to the issue. At sea he completed the discomfiture of the Royalists; then, turning his attention to the Dutch fleet, whose admirals in those days were giants, gave us the supremacy of the seas.

Blucher, Gebhard Lebrecht von
b. Rostock, Germany, 1742. d. Kirblowitz, Germany, September 12, 1819.

A soldier from boyhood, he considered himself neglected by Frederick the Great, and took to farming for fifteen prosperous years. Recalled by Frederick William II., he fought in innumerable battles, Jena, where he was a subordinate, among them. At Leipzig he had a great share in defeating the French, and at Waterloo appeared just in time to complete the overthrow of Napoleon, by whom he had only a few hours previously been defeated in the terrible battle of Ligny.

Boadicea
d. 62 A.D.

Queen of the Iceni, a British people living in Eastern England, Boadicea was robbed, at the death of her husband, King Prasutagus, of all her possessions, herself publicly whipped, and her daughters exposed to the brutalities of the Roman soldiers. She raised the Britons, captured Colchester, London, and St. Albans, and put to death, according to Tacitus, 70,000 Romans. The island would have been lost to Rome had not Suetonius Paulinus hastened from Anglesea with 10,000 disciplined soldiers. Boadicea's force of over 200,000 was powerless against the Roman legions, and suffered a terrible defeat. Thereupon Boadicea poisoned herself.

Boccaccio, Giovanni
b. Certaldo, Italy, 1313. d. Certaldo, December 21, 1375.

The "father of Italian prose" was the natural son of a merchant, and intended successively for commerce and canon law. The years which he devoted to those subjects were wasted, and much of his time in later life was taken up with diplomatic missions. The rise of Italian prose began

with his writings, and his influence is to be traced throughout the subsequent literature of Europe—in our own not least. Poets and novelists alike, from Shakespeare to Tennyson and George Eliot, have turned to him for inspiration. Licentiousness characterises some of his works, but others comprehend the loftiest ideals expressed in the noblest language.

Bodley, Sir Thomas
b. Exeter, March 2, 1545. d. London, January 28, 1613.

After having acted as Ambassador for several years, he devoted his talents and resources to re-establishing the library which Humphrey, Duke of Gloucester, had bequeathed to Oxford. This he so enriched with MSS. and books from all parts of Europe as to make it one of the finest in the world. It is called the Bodleian, in his honour.

Boerhaave, Hermann
b. Voorhout, Holland, 1668. Leyden, Holland, September 23, 1738.

The greatest physician and chemist of his time taught practically the whole of Europe. Peter the Great sat at his feet, and letters came to him from China seeking his advice. His works were translated into every European language, and even into Arabic.

Bolivar, Simon
b. Caracas, Venezuela, July 24, 1783. d. San Pedro, Colombia, Dec. 17, 1830.

The liberator of South America from the yoke of Spain saw the close of the French Revolution, and carried the revolutionary spirit with him back to Venezuela. After a protracted struggle with the Spaniards, he finally drove them out, and formed Colombia, Venezuela, New Granada, and Ecuador into a great Republic. Over this he ruled, while he was dictator of Peru. Bolivia, which was formerly Upper Peru, still commemorates him. His great Republic proved more than he could control, and he surrendered his office a few months before he died. He was the greatest patriot South America has known.

Bonaparte. See Napoleon

Borrow, George Henry
b. East Dereham, Norfolk, July 5, 1803. d. Oulton, Suffolk, July 26, 1881.

Leading a wandering life as a child with his father, who was a captain of Militia and moved with his regiment, Borrow, who acquired tongues and dialects with extraordinary facility, early mastered Irish, Danish, Welsh, French, German, Greek, and even Romany, the language of the gipsies, whose life and manners he has so fascinatingly described. His subsequent wanderings are related in his delightful "Lavengro," and his experiences as a representative of the Bible Society in "The Bible in Spain." At thirty-seven he married a wealthy widow, but was a rambler till late in life. Among his fourteen works are those which will last as long as the language.

Boswell, James
b. Edinburgh, October 18, 1740. d. London, May 19, 1795.

The man who immortalised Samuel Johnson and himself at the same time was a Scottish lawyer, son of Lord Auchinleck, a judge of the Court of Session. In his youth he travelled, and met Rousseau, Voltaire, and Paoli, the Corsican patriot. Coming to London, he met Johnson, which crowned his happiness. His "Life of Johnson" appeared seven years after his hero's death, and was an instant success. It was acclaimed the greatest biography in the language, and such it remains. Boswell gave way to intemperance in his later years, and died miserably. His "Life" was the one meritorious performance of his career, and that was meritorious indeed.

Botticelli, Sandro
b. Florence, Italy, 1447. d. Rome, May, 17, 1510.

Alexander Filipeppi was the name of this great Florentine artist, who, however, adopted the title of the goldsmith to whom his father apprenticed him. His training here in goldwork and jewellery was valuable to him in his painting. He studied under Fra Lippo Lippi, whose work he excelled. Botticelli's paintings, both in classical and religious veins, are marked by infinite delicacy, beauty, and care. Glorious examples are to be seen in the National Gallery. He was among the first engravers. Although he made large sums of money, he died in poverty.

Bougainville, Louis Antoine de
b. Paris, November 11, 1729. d. Paris, August 31, 1814.

A man who might have gained reputation as mathematician or philosopher, Bougainville's fame rests upon his having been the first son of France to circumnavigate the world. This he accomplished, 1766-69, in a frigate, accompanied by a transport, and lost only seven men out of a crew of two hundred. In his closing days he was honoured by Napoleon.

Bouguer, Pierre
b. Croisic, France, February, 10, 1698. d. Paris, August 15, 1758.

Mathematician, hydrographer, and geometrician, he devoted ten years of his life to measuring a degree of meridian near the Equator. He made important discoveries concerning the expansion and contraction of metals, the refraction and density of the atmosphere, the reciprocation of the pendulum, and the mode of measuring the force of light. To Bouguer we owe the foundation of photometry and the invention of the heliometer.

Boulton, Matthew
b. Birmingham, September 14, 1728. d. Birmingham, August 17, 1809.

He was the son of a Birmingham silver stamper and piercer, and improved the manufacture of art work in metal, pottery, etc. He converted a barren heath at Soho, Birmingham, into a great industrial establishment, and induced Watt to join him. They produced the steam-engines for which they were famous. In addition, they enjoyed unique reputation for the manufacture of coins. Patient industry, as well as genius, conduced to their success. Their manufacture of steam-engines was profitless for the first eighteen years of their association.

Bourgelat, Claude
b. Lyons, France, 1712. d. Lyons, 1799.

The father of veterinary science was intended for the law, but, disgusted at having gained a verdict in which his client was, to his knowledge, in the wrong, he joined a cavalry regiment, made a study of horses, and opened the first veterinary school in Europe.

Bourne, Hugh
b. Fordhays, Staffs, April 3, 1772. d. Bemersley, Staffs, October 11, 1852.

Dismissed from the Wesleyan body, of which he was a member, he established a little community, which has since grown to importance, under the name of Primitive Methodists. He worked for the greater part of his life as a carpenter, but carried his message throughout the United Kingdom and to the United States.

Bowring, Sir John
b. Exeter, October 17, 1792. d. Exeter, November 23, 1872.

We owe to Bowring much of our knowledge of the folklore of other nations. He was one of the greatest linguists the world has seen; was master of forty languages, and declared that he knew two hundred, and could speak one half that number. While he was supreme naval and military head at Hong Kong, his action in ordering fire to be opened on the Canton forts caused the "Arrow" war with China.

Boyle, Robert
b. Lismore Castle, Ireland, January 25, 1627. d. London, December 30, 1691.

The true precursor of the modern chemist, one of the founders of the Royal Society, and one of the greatest natural philosophers of his age, was the seventh son of the great Earl of Cork. He made experiments with an air-pump, which he improved, and important discoveries as to the properties of air and the propagation of sound. A

devout Christian, he caused the Bible to be translated into several foreign languages at his expense.

Bradley, James
b. Sherborne, Dorset, March, 1693. d. Chalford, Glos., July 13, 1762.

Though he took Orders, and was presented to two small sinecure livings, he did not give up his studies, his whole life being devoted to science. Six years after being appointed Savilian Professor of Astronomy, at Oxford, he made known his discovery of the aberration of light; following this by explaining the nutation of the earth's axis, whose inclination towards the ecliptic, he was able to show, is constant.

Brahe, Tycho
b. Knudstorp, Sweden, Dec. 14, 1546. d. Prague, Austria, Oct. 24, 1601.

Brahe studied astronomy when he should have been learning law, and made himself famous in a direction not desired by his parents. He did much to advance the science to which he was devoted, though his theory a modification of the Ptolemaic, and rejection of the Copernican was, of course, erroneous. Kepler was his pupil, and owed much to him.

Braidwood, Thomas
d. Edinburgh, 1715. d. London, October 24, 1806.

Braidwood was the first man in England to systematically teach the deaf and dumb. His school, opened in Edinburgh, was afterwards transferred to London, and its operations extended by his daughter-in-law, Isabella Braidwood, to Birmingham.

Braille, Louis
b. Coupvray, France, January, 1809. d. Paris, 1852.

Rendered blind by an accident when three years of age, Braille devoted his life to perfecting the beautiful system by which the sightless are enabled to read and write in relief.

Bramah, Joseph
b. Stainborough, Yorkshire, April 13, 1748 d. London, December 9, 1814.

Lame from an accident with which he met when sixteen years of age, he was compelled to quit work in the fields for cabinet-making, whence he passed to his true vocation—engineering. He invented many useful machines among them the hydraulic pump, sanitary apparatus, printing machinery for banknotes, fire-engines, and a famous safety lock. His boilers for steam-engines enjoyed a high reputation, and he was one of the first to suggest the screw propeller for steamships.

Bramante, d'Urbino (Lazarus)
b. Urbino, Italy, July, 1444. d. Rome, 1514.

Bramante relinquished painting to devote himself wholly to architecture, in which he had Raphael as a student. He was commissioned by Pope Julius II. to undertake the first part of one of the greatest enterprises in history the rebuilding of St. Peter's, Rome. He died before his work could be completed. Subsequently his designs were departed from by other architects; but expert opinion holds that had his plan been followed, the effect would have been more grand and impressive.

Brassey, Thomas
b. Barton, Cheshire, November 7, 1805. d. St. Leonards, December 8, 1870.

A man of scanty schooling, with no command of foreign languages, Brassey, who was the son of a small landowner, became head of the greatest industrial enterprises ever committed to the care of a single man. He built many railways, docks, and harbours in England; while, at the same time, his operations embraced the construction of railways in almost every country in Europe, India, Australia, Canada, and South America. He had an army of 75,000 workmen, whose wages represented from £15,000 to £20,000 every Saturday. He amassed enormous wealth, and made the fortunes of many of his subordinates. A man of simple, noble nature, he was in all his business relations scrupulously honest and just.

Breakspear, Nicholas (Pope Adrian IV.)
b. Abbot's Langley, Herts, 1100. d. Anagni, Italy, September 1, 1159.

The only Englishman to fill the Papal chair was the son of a poor clerk who turned monk, and left his son destitute. Nicholas used daily to attend the monastery at St. Albans; then, making his way to France, was received in a menial capacity into the house of the canons of St. Rufus, near Valence. Here he became prior and abbot; was then sent by the Pope to found a new archiepiscopal see for Norway, and at the death of Anastasius, in 1154, was himself elected Pope. He it was who gave Ireland to Henry II., that he might civilise the Irish, and bring them into the Roman Church. His reign was one long struggle for the temporal supremacy of the Papacy over contemporary sovereigns.

Bridgewater, Francis Egerton, Duke of
b. May 21, 1736 d. London, March 8, 1803

The "father of inland navigation in England" was so dull of intellect as a boy that his exclusion from the dukedom was seriously proposed. He built the first canal in this country dependent wholly upon an artificial waterway. It ran from Worsley to Manchester, and was forty-two miles in length. The canal uniting Manchester and Liverpool followed, and was so costly that at times its projector was glad to borrow a £5 note from his tenants. He spent in all nearly a quarter of a million on his canals, but before his death benefited from them to the extent of £80,000 a year.

Brindley, James
b. Chapel-en-le-Frith, Derbyshire, 1716 d. Turnhurst, Staffs, Sept. 30, 1772.

The unlettered son of a ne'er-do-well, built the Bridgewater and other canals, the first of their kind in England. He was a genius who worked for a guinea a week. The schemes for the canals he fashioned in his head; he could never draw or write. Troubled by a problem, he would retire to bed and think it over, when all would come right.

Broadwood, John
b. Cockburnspath, Scotland, 1732 d. London, 1812

Having walked from Scotland to London to seek to make his fortune as a cabinet-maker, Broadwood took service with Burkhardt Tschudi, a Swiss harpsichord-maker. He married the daughter of the latter, and, becoming possessor of the business, won fame throughout Europe for his pianos.

Brontë, Charlotte
b. Thornton, Yorks, April 21, 1816. d. Haworth, Yorks, March 31, 1855.

Charlotte was the eldest of a family of four, of whom her brother, Patrick Branwell Brontë, a profligate, with some touch of the family genius, died of consumption. Her father was an eccentric, selfish clergyman. Her sisters Anne and Emily Jane like herself, were delicate, but shared her talent. They published jointly a little book of poems, but had to seek livelihood as governesses. This failing, Emily wrote her famous "Wuthering Heights," and Charlotte, having had the "Professor" rejected, commenced at once "Jane Eyre," which met with instant success. Anne produced "Agnes Grey." Charlotte's brother and two sisters died within a short time of each other, and she was left to attend to her father, and continue her literary work, uncheered. She married, in 1854, the Rev. A. B. Nicholls, who had been her father's curate, but died in the following year. The story of the three sisters is one of the saddest in literature. Genius was never nurtured in more dispiriting, uncongenial conditions.

Brown, John
b. Torrington, Connecticut, May 9, 1800. d. Charlestown, Virginia, Dec. 2, 1859

The famous agitator for the abolition of slavery in America was of pilgrim stock, and lived as tanner, land-surveyor, and farmer until he devoted himself to anti-slavery propaganda. It was rough work, and bloody. Brown had five pro-slavery men shot, and, after organising an asylum in the

mountains of Virginia for runaway slaves, attacked the Harper's Ferry armoury in Virginia. He was taken, tried, and hanged, but his life was not given in vain. His rough efforts aided enormously in the crusade against slavery, while his death was an even more powerful factor in the scale.

Browning, Robert

b. London, May 7, 1812. d. Venice, December 12, 1889.

Endowed with many gifts, with some talent for drawing, and a taste for musical composition, Browning could rhyme almost as soon as he could talk. He had written a little volume of poems before he was twelve, and finished his dramatic poem "Pauline" by the time he was nineteen. The best known of his shorter poems were written before he was five-and-thirty. After his marriage to Elizabeth Barratt herself the most imaginative poetess that has yet appeared in England, perhaps in Europe he settled in Florence, but returned, a widower, to London to publish his masterpiece, "The Ring and the Book." He died in Venice, but is buried in Poets' Corner, Westminster Abbey. Obscure and difficult as Browning often is, he stands high among the poets of all time. It has been well said that whereas Wordsworth would lead the soul through nature to rest, it is through the spiritual struggles of the soul itself that Browning reveals the divine touch that discloses the true end of living and thinking.

Bruce, James

b. Kinnaird, Stirlingshire, December 14, 1730. d. Kinnaird, April 27, 1794.

Intended first for the Church, next for the law, Bruce was for a time a wine merchant before the fascination of the East inspired by his knowledge of Arabic, led to his taking the Consulate at Algiers. Seeking the source of the Nile, he discovered that of the Blue Nile, a matter in which, however, he had been anticipated. His travels and adventures in Abyssinia and Egypt, extending over six years, were set forth, upon his return home, in five volumes. So remarkable were his stories that he was generally discredited, though subsequent travel has handsomely vindicated him. In stature a giant, and a man of fine courage and delightful nature, he has been described as the poet, and his work the epic, of African travel.

Brunel, Isambard Kingdom

b. Portsmouth, April 25, 1806. d. London, September 15, 1859.

The only son of Sir Marc Isambard Brunel, he inherited much of his father's genius, and heroically assisted in the building of the Thames Tunnel, a labour of almost unparalleled difficulty and trial. In business for himself, he built many notable bridges, and laid the Great Western railway-track. His was the first steamship the Great Western regularly engaged in traffic between Great Britain and America. Afterwards he built the Great Eastern, the leviathan of her time, which was useful in laying submarine cables. Like his father, he was a man of lovable character and an unselfish, unswerving friend.

Brunel, Sir Marc Isambard

b. Hacqueville, France, April 24, 1769. d. London, December 12, 1849.

One of the most versatile geniuses of any age, Brunel the elder spent seven years of his youth at sea, then was driven by the French Revolution to America, where he took up civil engineering, and became the chief engineer of New York. Coming to England, when thirty years of age, to offer an invention to the Admiralty, he married an English lady, and made his home here. His invention was a machine for making ships' blocks, which saved the Government £24,000 a year. Afterwards he executed important works at the arsenals and dockyards, built great sawmills, and invented machinery for boots, printing processes, writing and drawing-machines, a knitting-machine, and a marine engine. In spite of his genius and industry, he was for months a prisoner for debt. His crowning achievement was the building of the Thames Tunnel, for the purpose of which he invented his famous shield. Nearly twenty years elapsed before the work was completed, but he lived to see the triumphant end of his labours.

Bruno, St.

b. Cologne, 1030. d. Calabria, Italy, October 6, 1101.

As superintendent of all the schools of the Diocese of Rheims, he had many distinguished pupils, among them the future Pope Urban II. He is chiefly notable, however, as the founder of the famous Carthusian Order, which he established upon withdrawing to the desert of Chartreuse.

Brunton, William

b. Dalkeith, Scotland, May 6, 1777. d. Camborne, Cornwall, Oct. 30, 1851.

The son of a watch and clockmaker, he worked first at Arkwright's mills, then under Boulton and Watt at Birmingham, where he became a foreman. When over sixty, he lost all his money through a disastrous speculation in business, but recouped himself. His inventions comprised many useful, and some fantastic, ones. Of the latter there was a walking-machine, called the steam-horse, which for a year carried loads up a steep gradient, but then exploded, killing thirteen people. His work in connection with steam navigation, however, was of primary importance. Some of the original engines used on the Humber and Mersey were of his design; while the Sir Francis Drake, the first steamer which ever towed a war vessel, was fitted out by himself.

Buddha

b. Kapilavastu, India, 480 B.C. d. Kusinagara, India, 400 B.C.

Only approximate dates can be given. His real name was Siddhartha, and he was the son of Siddhartha Gautama, raja of the Sakya clan, whose home was near Oudh. When nineteen he married his cousin, a princess, but renounced luxury and family joys to go for six years into the wilderness and study under learned Brahmans, practising severe penances the while. It dawned upon him one day that salvation was not to be sought in isolation, but in self-conquest and universal loving kindness. That instant he became consciously Buddha, which means "enlightened." He returned to his family, began his teaching at Benares, and travelled far and near, inculcating his doctrines. His converts were numerous, and to-day his religion is the faith of 500,000,000 people, half as many again as the whole of professing Christians.

Buffon, George Louis, Comte de

b. Montbard, France, September 7, 1707. d. Paris, April 15, 1788.

The son of a wealthy lawyer, Buffon devoted his whole life to the study of natural history, his great work upon which, though perhaps over-praised by his contemporaries, remains a wonderful achievement, considering the condition of scientific knowledge in the eighteenth century. He was a forerunner of Darwin, in that he takes a distinct place in the history of the doctrine of evolution.

Bunsen, Robert Wilhelm

b. Gottingen, Germany, March 31, 1811. d. Gottingen, August 16, 1899.

The co-originator, with Kirchhoff, of spectrum analysis, which opened a new world to chemists and astronomers, was one of the most painstaking men that ever lived. Although he destroyed the sight of one eye, and nearly poisoned himself by his experiments, he succeeded, by applying science to commerce, in effecting great reforms in the manufacture of iron, in inventing the burner which bears his name, the charcoal pile and the magnesium light, and many other valuable processes.

Bunyan, John

b. Elstow, Bedfordshire, November, 1628. d. London, August 31, 1688.

The son of a tinker, and himself trained to the same trade, Bunyan had but little schooling; and his experience as a soldier, when he was drafted into the Parliamentary Army, does not seem to have improved him. At the time of his marriage he was "the ungodliest fellow for swearing" his

friends had ever heard. His wife brought him for dowry two pious books; and the study of these, assisted by her own influence, effected his ultimate reformation. He became a powerful preacher. Nonconformist ministers of the Gospel coming under the official ban, he was cast into prison. He remained for some twelve years in the Bedford County Gaol, where he wrote several works. His release at last secured, he resumed his preaching, but was cast again into gaol, remaining a prisoner for six months. It was during this second incarceration that he wrote the first part of his deathless "Pilgrim's Progress." This, with "Grace Abounding" and "The Holy War," will live as long as religion has a literature. It has been translated into practically every known language, and fault will not be found with the dictum of Macaulay: "There is no book in our language on which we would so readily stake the fame of the old unpolluted English language; no book which shows so well how rich that language is in its own proper wealth, and how little it has been improved by all it has borrowed."

Burdett-Coutts, Angela Georgina, Baroness
b. London, April 21, 1814

The daughter of Sir Francis Burdett, M.P., she succeeded, at twenty-one, to the vast fortune of her grandfather, Thomas Coutts, through his widow, who had been an actress, but died Duchess of St. Albans. Made a baroness in her own right, she devoted her life to noble works. She built churches, founded three Colonial bishoprics, instituted official inspection of schools, equipped topographical surveys of the Holy Land, helped to establish Rajah Brooke in Sarawak, assisted emigration and war funds, formed many charitable institutions, built Clare Market, and model lodging-houses. Her career of goodness is almost without parallel in the history of Englishwomen.

Burke, Edmund
b. Dublin, January 12, 1729 d. Beaconsfield, Bucks, July 8, 1797.

His father was a Protestant lawyer, his mother a Roman Catholic, and his first schoolmaster a Quaker -a combination of factors which early taught him the lesson of religious toleration. Entered at Trinity College, Dublin, he studied industriously, if without system, and settled in London to study law. This career he abandoned for literature and politics. He was successively secretary to "Single-speech Hamilton," at that time Secretary for Ireland, and to the Marquis of Rockingham, Prime Minister. He did not hold office until he was fifty-three, and then for a brief period was Paymaster of the Forces. His influence with pen and tongue had no relation to office. His knowledge of public affairs was inexhaustible, his sympathy with the oppressed unfailing. As an orator, he ranks among the greatest produced by this country, though his glowing imagination, his eloquent diction, and passionate delivery did not greatly appeal to the men of his day. His speech at the opening of the trial of Warren Hastings is regarded as perhaps the finest ever delivered in our language; while those attacking the action of the Ministry in regard to our American Colonists, and condemning the French Revolution were, like his writings upon the same subjects, scarcely less resplendent examples of argument and eloquence.

Burns, Robert
b. Alloway, Ayrshire, Jan. 25, 1759. d. Dumfries, July 21, 1796.

The eldest of the seven children of a small farmer, "the boast of Scotland," as Scott named him, received but the meagrest education. At thirteen he was threshing corn for his father, whose chief labourer he became two years later. Before he attained to manhood, he managed to improve his handwriting, and to master French. Latin was too much for him. His first poem was written before he was seventeen, being inspired by a girl with whom he worked in the fields. For a time he studied land-surveying under his uncle; but this, like a subsequent venture in flax-dressing, had no material result. At the death of his father he attempted, with a brother, the task of working an impossible farm. Meantime, he was writing verse. None was published until he had accepted the post of estate-overseer in Jamaica, at £30 per year. His first volume of poems, containing some of his most popular pieces, was issued to pay his passage. Happily, the work came into the hands of Blacklock, the blind poet, who, in a friendly letter, persuaded the friendless youth to abandon his plan of emigrating. The call for a second edition took him to Edinburgh, where he was introduced into the best society of the place. He carried himself with modesty and dignity, and was not spoilt by the admiration he inspired. Determining to "woo his muse at the plough-tail," he took a farm, and, married now to Jeane Armour, sought to make ends meet from this venture, coupled with an Excise Commissionership. The latter yielded him only a clear £40, and at best not more than £70. It had the effect of developing his affinity for evil company, and hard drinking and disregard of health ruined his constitution, and brought him to an untimely grave. His private life was not creditable. That his genius should have burned so brightly under conditions so debasing is greatly surprising. He wrote with remarkable facility. "Tam o' Shanter" was composed during a walk by the Nith; the "De'il's awa' wi' the Exciseman" during a wait by the seashore, and "Scots wha hae" while riding in a storm over the wilds of Kenmure. His works are for all time. "He left his land her sweetest song, And earth her saddest story."

Burton, Sir Richard Francis
b. Barham House, Herts, March 19, 1821 d. Trieste, Austria, Oct. 20, 1890

This daring traveller and indefatigable writer went, disguised as a Mohammedan, to Mecca, and, seeking the sources of the Nile, discovered Lake Tanganyika. Speke, who accompanied him, was sent to explore another lake, and found in it the true source of the Nile Lake Victoria. Burton, who was for many years in the Consular Service, was a roamer almost to his life's end, and was a pioneer in lands which have since become familiar to travellers.

Byron, George Noel Gordon, Lord
b. London, Jan. 22, 1788 d. Missolonghi, Greece, April 19, 1824

Succeeding his grand-uncle in the title and estates, which latter included Newstead Abbey, he studied at Harrow and Cambridge, publishing, when nineteen, "Hours of Idleness." An adverse criticism of this in the "Edinburgh Review" called forth his "English Bards and Scotch Reviewers," published before he had completed his twenty-first year. After Continental travel he married, at twenty-seven, Anne Isabella Milbanke. Their daughter, who afterwards became Countess of Lovelace, was born the same year, and he and his wife parted, under mysterious circumstances, two months afterwards. Byron left England in 1816, and spent some years in Italy, where he took an active interest in the revolutionary movement of the Carbonari. In 1823 he threw in his lot with the Greek insurgents at Cephalonia, became in the following year Commander-in-Chief at Missolonghi, and there died of fever. He died when his intellectual powers were at their zenith. His best known works are "Childe Harold"; a series of dramatic poems, including "Manfred," "Cain," and "Marino Faliero"; also "Mazeppa," "Beppo," and "Don Juan." There remain indelible blots upon his fame as a man, but his nature had its grand and noble and heroic side. His works reflect himself. His poetry is a "dark but divine revelation," and from the dictum of Goethe, that here was a true poet, none now is found to differ.

Cabot, Sebastian
b. Bristol, 1474. d. London, 1557.

The second son of John Cabot, he, with his father, was the first European to see the mainland of North America, anticipating Columbus and Amerigo Vespucci. He sailed from Bristol, and traced the American sea-coast for eighteen hundred miles. Employed at the Spanish Court for some time in correcting maps and charts, he settled down in England as Grand Pilot. His name is also associated with heroic efforts for the discovery of other places not then clearly defined upon the map. He was the first to explain in England the variation of the magnetic needle.

Cadmus

It is difficult to separate legend from the history of the founder of Thebes, in Bœotia. As to his birth and death, dates cannot be given; nor can it be determined whether he was of Phœnician or purely Greek origin. He is credited with having introduced into Greece the Phœnician characters whence was derived the alphabet, the foundation of Western civilisation. Cadmus, the Milesian, the first Greek who wrote history in prose, is supposed to have flourished in the reign of Halyattes in Lydia.

Cæsar, Julius
b. Rome, July 12, 100 B.C. d. Rome, March 15, 44 B.C.

"The foremost man of all this world" was the son of a Roman prætor, or consul. He began his career at twenty, when he was fighting in Mytilene. He was captured by pirates two years later, but, gaining his liberty, rose rapidly to eminence, and, with Pompey and Crassus, formed the first triumvirate. He invaded Britain, then devoted ten years of his life to the complete subjugation of Gaul. So complete was his conquest, and so beneficent his rule, that France was proud of her conqueror. She remained Romanised, she Romanised Germany, and in time sent forth Charlemagne and William the Conqueror. Meanwhile, Cæsar had great battles to fight against the armies of Pompey and Vercingetorix, and, though not invariably successful, finally redeemed Rome from the clutches of an evil oligarchy, and subjected the Empire to his own personal rule. He reformed the calendar, re-cast the administration, and, by a multitude of measures, proved himself as great an administrator as he was a scholar, orator, and soldier. His three and a half years' rule was a period of marvellous achievement for the progress of the world. He was assassinated by conspirators whom he had befriended jealous men who asserted that he desired to make himself hereditary ruler.

Calderon de la Barca, Pedro
b. Madrid, January 17, 1600. d. Madrid, May 25, 1681.

Spain's greatest dramatist was educated as a Jesuit, and was for ten years a soldier before receiving a Court appointment. Afterwards he rejoined the Army, then entered the priesthood, and was, after a further ten years, recalled to Court. He now wrote the plays which his warmest admirers aver entitle him to rank as the "fourth in a mighty quaternion, with Homer, Dante, and Shakespeare."

Calvin, John
b. Picardy, France, July 10, 1509. d. Geneva, May 27, 1564.

The most eminent of the Protestant reformers after Luther embraced the Reformation when nineteen years of age, was banished from Paris three years later; published his famous "Institutes" in 1536 and fled the same year to Geneva. Only two years' rest here was permitted him, for he was banished in 1538, returned three years afterwards, and initiated the Academy of Geneva in 1539. Calvin's services to the cause of Protestantism were inestimable, and his intolerance was not unacceptable in the age in which he so prominently figured. He was a great scholar, a social legislator, and a man distinguished throughout his career by his sincerity and purity of life.

Cano, Juan Sebastian Del
b. Guetaria, Spain, about 1460. d. August 4, 1526

One of Magellan's captains, he succeeded his leader. He was the first man to sail round the world, completing his voyage on September 6th, 1522. He died at sea when on a further expedition.

Canova, Antonio
b. Possagno, Italy, November 1, 1757. d. Venice, October 13, 1822.

From his boyhood he showed his talent for modelling, and at seventeen made himself famous by his statue of Orpheus and Eurydice, which brought him notable commissions. His fame increased with his years. Noble examples of his works are to be seen in the galleries of the Continent. He visited England to pronounce upon the merit of the Elgin marbles.

Canton, John
b. Stroud, Gloucestershire, July 31, 1718. d. March 22, 1772.

Apprenticed to a broadcloth weaver, and afterwards engaged as a schoolmaster, Canton was acclaimed in his day "one of the most successful experimenters in this golden age of electricity." He was the first to show that air may receive electricity by communication, and that water is compressible; he also first manufactured powerful artificial magnets. Nobody in his era did more to advance public knowledge of electricity.

Caracci, Ludovico
b. Bologna, Italy, April 21, 1555. d. Bologna, November 13, 1619.

The son of a butcher, he established the famous Bologna school of painting, and left many fine works. The Caraccis, Agostino and Annibale were his cousins. The last-named, a tailor, eclipsed the works of Agostino, and even of his teacher.

Caravaggio, Michelangelo Amerighi da
b. Caravaggio, Italy, 1569. d. Porto Ercole, Italy, 1609.

A painter of the naturalistic school, two of whose most famous works—"Christ and the Disciples" and "The Entombment of Christ"—are respectively in the National Gallery and the Vatican, he was the son of a mason. The fact that he was guilty of murder may have invested his works with the wild and gloomy character for which they are noted.

Carey, William
b. Paulerspury, Northants, August 17, 1761. d. Calcutta, June 9, 1834

One of the first two Baptist missionaries to India, he was by trade a shoemaker. He proved to have a remarkable faculty for languages, and under his superintendence the Scriptures were published in nearly two score Oriental tongues. He founded the famous Serampur Mission in 1799.

Carlyle, Thomas
b. Ecclefechan, Dumfriesshire, Dec. 4, 1795. d. Chelsea, Feb. 4, 1881.

This sturdy prophet, in the guise of a man of letters, was the son of a worthy stonemason, was educated at Annan Grammar School and Edinburgh University, and maintained himself, while studying law, by giving lessons in mathematics and by writing for encyclopædias. He married, when thirty-one, Jane Baillie Welsh, a woman noted for her wit and beauty. Genius and domestic bliss, unfortunately, are not invariably found beneath the same roof, and the married life of this gifted couple was not happy. Carlyle settled, in 1834, in Chelsea, and there resided to the time of his death, affectionately styled the Sage of Chelsea. There he wrote the works by which he will always be known—"Cromwell," the "French Revolution," "Sartor Resartus," his "Life of Schiller," and translations of that poet's works, and so forth. Chronic dyspepsia aggravated a naturally intolerant, irascible

temperament; but while his faults were hidden from none, his virtues, his nobility of character, his hatred of deceit and meanness and dishonesty were acknowledged even by those at whose foibles he hit hardest. He accepted the Prussian Order of Merit upon the publication of his "Life of Frederick the Great," but refused the pension and decoration which Disraeli offered.

Cartwright, Edmund

b. Marnham, Notts, April 24, 1743. d. Hastings, October 30, 1823.

The inventor of the power-loom and of the wool-comber was a clergyman, who held one or two livings, and, further, was domestic chaplain to two Dukes of Bedford. His inventions, though eventually successful, and of value to the woollen industry, were not productive of profit to himself - partly from their own defects, but chiefly from the prejudice which existed in the minds of workmen. Late in life he received a grant of £10,000 in recognition of his services to trade.

Cary, Henry Francis

b. Gibraltar, December 6, 1772. d. London, August 14, 1844.

The one achievement which entitles Cary to fame is his translation of Dante. It took him many years, and the work was for some time ignored. Coleridge's enthusiastic recognition gave it fame, and its author more fit reward. But he was always in pecuniary difficulties until within three years of his death, when a small pension was conferred upon him. When Cary was translating Dante, Napoleon said of the poet: "His fame is increasing, and will increase, because no one ever reads him." Cary has given Dante immortality in England because everybody does read him—in Cary's meritorious translation.

Catharine the Great

b. Stettin, Prussia, May 2, 1729. d. St. Petersburg, November 17, 1796.

Catherine was one of the most talented and most wicked sovereigns Russia has known. She caused her husband, Peter III., to be deposed and assassinated, and usurped the throne. Next, Prince Ivan, upon whom the hopes of the nation were set, was assassinated. Her private life was scandalous, but her career as a sovereign was in many particulars exemplary. She introduced new laws, reformed the administration, encouraged learning, and left it truly to be said that no sovereign save Ivan the Terrible had so extended the Empire. She had given Russia for boundaries the Niemen, the Dniester, and the Black Sea.

Caxton, William

b. Kent, about 1422. d. Westminster, 1491.

The first English printer was a mercer, who served his apprenticeship in London, and then was for many years resident in Bruges, where he became the head of a company regulating the operations of English merchants in the Low Countries. In 1469 he translated into English the "Recuyell of the Historyes of Troye," and, the demand for the book being so great, he had recourse to printing, which art he had learnt in Bruges. The first book, however, of which we have definite knowledge as to its having been printed at the press which he established in Westminster is the "Dictes and Sayinges of the Philosophers." This made its appearance in 1477.

Cellini, Benvenuto

b. Florence, November 10, 1500. d. Florence, February 13, 1571.

Famous as sculptor, engraver and goldsmith, Cellini devoted the early part of his life to the work of a goldsmith. He was present in Rome during its siege and sack by the Constable de Bourbon. Cellini asserts that he fired the cannon which killed Bourbon and wounded the Prince of Orange. He experienced wonderful vicissitudes - committed murder, was imprisoned, escaped, to renew his fame in fresh directions, in sculpture and engraving. His autobiography is one of the most remarkable works of the character extant, and enjoys universal fame.

Cervantes-Saavedra, Miguel de

b. Alcalá de Henares, Spain, 1547. d. Madrid, April 23, 1616.

The author of "Don Quixote" is supposed to have been educated at the University of Salamanca. He served, however, as a common soldier, and at the Battle of Lepanto, 1571, was so injured as permanently to lose the use of his left hand and arm. The galley in which he was returning to Spain was captured by pirates, and he was detained as a slave for five years in Algiers. After he had been ransomed, it is supposed that he was imprisoned in connection with a debt, and while actually in prison wrote the first part of his immortal work. Upon its publication it leapt at once into popularity; but he did not soon write the second portion, preferring other works, which, while they show the versatility of his genius, are scarcely to be compared with his masterpiece. "Don Quixote" places him in the forefront of the greatest writers the world has known.

Chalmers, Thomas

b. E. Anstruther, Fifeshire, March 17, 1780. d. Edinburgh, May 31, 1847.

This celebrated Scottish author and divine was the father of the Scottish Free Church. He had collected £300,000 for building new churches, and, the dispute over patronage being very keen, he, with 470 other ministers, quitted the parent church and established the new.

Chambers, William

b. Peebles, Scotland, April 16, 1800. d. Edinburgh, May 20, 1883.

The son of a cotton-manufacturer, he, with his brother Robert, founded the publishing-house bearing their name, from which works of the highest educational value to the nation have been issued. The brother, Robert Chambers, who was two years the junior of William, and died in 1871, was the author of many acceptable works. The most notable his "Vestiges of Creation," published anonymously prepared the way for Darwin's "Origin of Species."

Chantrey, Sir Francis Legatt

b. Norton, Derby, April 7, 1781. d. London, November 25, 1841.

Left fatherless when twelve years of age, this son of a carpenter worked in the shop of a Sheffield carver and gilder for five years, then was able to take lessons at the Royal Academy. Having carved a marble bust for a Sheffield church, and others for Greenwich Hospital, he rapidly made himself famous, and executed some of the finest statuary ever done by an English sculptor. He left a fortune of £150,000, from the interest of which our national treasures should be each year enriched, the sum being bequeathed to the Royal Academy.

Charlemagne

b. April 2, 742. d. Aachen, Germany, January 28, 814.

Charles the Great, King of the Franks, Roman Emperor, was the son of Pepin the Short, and succeeded jointly with his brother to the throne of the Frankish kingdom. Upon his brother's death he took the crown to himself. He was a great soldier, a scholar, a born administrator, and the most enlightened ruler of his time. His wars were long and many, but wherever he went the Christianising of his conquered subjects was a paramount consideration. He was crowned Emperor of the Romans in St. Peter's on Christmas Day, 800. His empire extended from the Ebro to the Raab, and from the Eider to the Garigliano, but after his death it was frittered away.

Charles I.

b. Dunfermline, Scotland, November 19, 1600. d. London, January 30, 1649.

This ill-fated monarch takes his place in the gallery of fame not as a great, good, or wise man, but as one whose acts and ends made him the most conspicuous sovereign in our annals. He succeeded his father, James I., on March 27, 1625, and three months later married Henrietta Maria, a Catholic Princess of the Royal House of France.

Persuaded of the divine right of kings, he essayed to govern without Parliament, meeting the expenses of government by forced loans, poundage and tonnage, ship money, and other unconstitutional sources of revenue. His attempts to anglicise the Church of Scotland brought about the Solemn League and Covenant, and led to a bloodless civil war. Parliament, which had not sat for years, was summoned, and the Long Parliament outlasted the King. The revolutionary war extended over four years, and ended in his being taken, impeached, and executed.

Châteaubriand, François René, Vicomte de

b. St. Malo, France, September 14, 1768. d. Paris, July 4, 1848

This celebrated French statesman and man of letters began his career in the army, and after visiting America fought with the Royalist forces at Thionville. Under Napoleon he accepted office, which he relinquished upon the murder of the Duc d'Enghien. Having previously spent some years in England, he now travelled extensively, afterwards supporting the Restoration Monarchy. He was made a peer, and ambassador to England, but revolted against the Royalists until the downfall of Charles X. His writings were many, various, and, for the most part, excellent. He has been called the "Father of the Romantic School."

Chatham, Earl of

b. Westminster, November 15, 1708. d. Hayes, Kent, May 11, 1778.

First a cornet in the Dragoons, William Pitt the elder entered Parliament in 1735, and allied himself with the Prince of Wales, who was then in opposition to the King. Upon the defeat of Walpole he filled minor offices, and in 1757 formed a coalition with the Duke of Newcastle, in which the latter was nominally Premier, while Pitt was so in actuality. His policy of conducting the war against France formed one of the most brilliant chapters in our history, the French being everywhere beaten—in India, in Canada, in Africa, in Europe—on sea and land. He was compelled to resign when his Ministry would not support him in his determination to declare war against Spain. He was Premier again, this time as Viscount Pitt and Earl of Chatham; but his Ministry was helpless without the aid which his ill-health prevented his affording, and his power was gone. He vehemently condemned the policy pursued by this country towards the American Colonies, but was struck down by fatal illness in the House of Lords when declaring against the proposition to terminate the war by granting the Colonists unconditional freedom.

Chatterton, Thomas

b. Bristol, November 20, 1752. d. London, August 24, 1770.

The saddest soul in the history of letters had not completed his eighteenth year when he took his life in a miserable garret in London. Yet how many poets of a later day have his works inspired! He was the son of a sub-chanter at Bristol Cathedral, who left no provision for his boy. Chatterton was bound apprentice to an attorney, in whose house he lived the life of a menial. In his twelfth year he produced the first of the famous "Rowley" poems—his own creation, but which he represented as having been found by himself in the muniment-room of Bristol Cathedral. More followed, and upon his coming to London, and earning eleven guineas, fortune seemed within his grasp. He wrote poems, squibs, stories, essays, letters. "It was Ossian, or a Saxon monk, or Gray, or Smollet, or Junius; and if it failed in most what it affected to be—a poet of the fifteenth century—it was because it could not imitate what had not existed." His patron, Lord Mayor Beckford, died, and, his application for a post as ship's surgeon failing, he was left penniless. He refused a meal offered to him in charity, and took poison.

Chaucer, Geoffrey

b. London (?), 1340. d. London, October 25, 1400.

Chronologically, Chaucer is the first of English poets, and is called the "Father of English Poetry." In point of merit he is among the first of all our poets. He bore arms for twenty-seven years, and was employed on many missions to the Continent. This enabled him to study the Italian poets, by whose example he was inspired. His best known work is "The Canterbury Tales." At later periods of his life he enjoyed considerable Court patronage, but his career was chequered, though not sufficiently to daunt his spirit or extinguish his genius. He was the son of a London vintner and innkeeper.

Cheops

b. 3095 B.C. d. 3032 B.C.

Authorities differ to the extent of two thousand years as to the age in which lived Khufu, the Egyptian King, commonly known as Cheops. He was neither a great man nor good, but he can never be forgotten so long as his vast pyramid at Gizeh, Egypt, exists. It was built for his sepulchre by the labour of hundreds of thousands of slaves, spread over a period of thirty years, and remains to-day the greatest stone building in the world, containing, it is estimated, six million tons of masonry. Cheops was impoverished by the cost of his tomb, and to raise money, it is said, sacrificed the honour of his daughter.

Chesney, Francis Rawdon

b. Annalong, Down, March 16, 1789. d. Mourne, Ireland, January 30, 1872.

A British general and engineer, he established an overland route to India, explored the valley of the Euphrates, and demonstrated the feasibility of a Suez Canal in a report which served De Lesseps as starting-point.

Chevreul, Michel Eugène

b. Angers, France, August 31, 1786. d. Paris, April 9, 1889.

He was for over sixty years chemist at the Gobelins factory, and professor at the French Museum of Natural History. From his labours vast industries have been brought into existence, among his most important discoveries being margarine, olein, and stearin.

Chopin, Frédéric François

b. near Warsaw, Poland, March 1, 1809. d. Paris, October 17, 1849.

Into the forty years of this famous composer and pianist's life was crowded a vast amount of composition—songs, dances, and greater works for the piano—which will long keep his memory green. His association with the famous George Sand extended over eight years. He is the "Prince Karol" of her novel "Lucrezia Floriani," in which she represents him as a "high-flown, consumptive, exasperating nuisance."

Cicero Marcus Tullius

b. Arpinum, Italy, January 3, 106 B.C. d. Formiæ, Italy, December 7, 43 B.C.

One of the greatest orators of his age, Cicero established his reputation as a speaker in his twenty-sixth year, and at thirty pronounced, in denunciation of the infamous Verres, the noble oration which has been preserved to us. As a statesman, Cicero was not robust of will; and, regarded as a trimmer and time-server, he was banished and his house sacked. He was recalled to Rome, but hovered between allegiance to Cæsar and Pompey, finally inclining to the former. He was assassinated in consequence of his indictment of Antony. Inconsiderable as politician and statesman, Cicero excelled as orator and man of letters, and his writings and speeches are dear to all scholars.

Cleopatra

b. Alexandria, 69 B.C. d. Alexandria, 30 B.C.

The last Queen of Egypt was a woman of surpassing beauty and of highly-cultivated mind. She inherited the throne of Egypt jointly with her brother, Ptolemy Auletes, but his guardians denied her right. Cæsar, arriving at this time in

Egypt in pursuit of Pompey, was captivated by her beauty and address, and made successful war in her behalf. She accompanied him back to Rome, and there bore him a son, who was afterwards assassinated by Octavianus.* In the tumult which followed the murder of Cæsar she returned to Egypt, to be summoned to meet Antony at Tarsus, in Cilicia. Antony was not proof against her beauty, and his devotion to her brought about his ruin. He spent the winter with her in Alexandria, then went to Rome to divorce his wife, the sister of Octavian, who thereupon declared war against Cleopatra. Antony joined her, and lost the Battle of Actium. Cleopatra fled, and he, to follow her, threw away half a world. Octavian appeared with his host before Alexandria; and Antony, hearing the false report that Cleopatra was dead, fell upon his sword, while she, to avoid being exhibited at Rome in the triumph of Octavian, took her own life.

Cobden, Richard

b. Heyshott, Sussex, June 3, 1804. d. London, April 2, 1865.

He began life in the warehouse of an uncle, whom he served as clerk and traveller; then, with two others, started a business of his own in London, with calico-printing works in Lancashire, which led eventually to his settling in Manchester. He visited the United States and the Levant, and began his campaign against the Corn Laws. The Anti-Corn Law League, born in Manchester, had Cobden at its head. He preached Free Trade in Parliament and out, and it was due mainly to him and his followers that the Corn Laws were abolished. His devotion to public affairs ruined his business, and, out of gratitude for his services, a national subscription of £80,000 was presented to him. He negotiated an important commercial treaty between France and England, and did useful work for the North in the American Civil War.

Coleridge, Samuel Taylor

b. Ottery St. Mary, Devon, October 21, 1772. d. London, July 25, 1834.

The son of a vicar, who was also a schoolmaster, Coleridge showed as a boy a wonderful avidity for learning, but he left Cambridge without a degree. He got into debt, enlisted, was bought out, acted as editor, lecturer, preacher, and wrote some poems. With Wordsworth, he wrote "Lyrical Ballads," contributing the immortal "Ancient Mariner." Meanwhile, he had married Southey's sister-in-law, and projected, with his two poet friends, a barren scheme for a settlement in the wilds of America. Accepting a pension from the Wedgwoods, he studied for some time in Germany, and upon coming back established himself at Keswick with Southey, and with Wordsworth for neighbour. Here his craving for opium asserted itself, and eventually mastered him. It ruined him mentally and morally. He went to London, where he lectured with varying success on Shakespeare and the fine arts. In London his declining days were passed. His conversational powers were remarkable, and he had many and true friends. As a poet he ranks high, and he was a notable critic. To English literature he rendered invaluable service by infusing into it the spirit of German learning.

Columbus, Christopher

b. Genoa, Italy, about 1435 or 1446. d. Valladolid, Spain, May 20, 1506.

This, one of the most fascinating of all life-stories, began in the humble cottage of a wool-carder. To the same trade as his parent the son was bred, but at a tender age took to the sea. He managed to acquire knowledge of subjects not commonly known at that time, and during all the adventures of his early days—his fights and hair-breadth escapes at sea—this was germinating in his brain, until, arriving at maturity, he resolved upon an attempt to reach India by sailing westward over the open sea. Years elapsed before he could gain the support necessary to equip his ships; but, after heart-breaking discouragements, he set sail, August 3rd, 1492, into the unknown. The wind was fair, and his crew inferred that it always blew in that direction, and, therefore, that they would never be able to return. The variation of the needle, with every other new phenomenon, terrified his crews, who were repeatedly on the point of mutiny. But he held bravely on, and on October 12th, 1492, reached the Bahamas, discovering during his three months' stay Hayti and Cuba. To the whole he gave the general name of the West Indies, so recording his belief that he had reached the Indian Sea. Returning with a greater fleet in the following year, he added little to his first discovery; but at the third attempt, in 1498, he first reached the American continent, near the mouth of the Orinoco. And now, at Hayti, he found the colony which he had established in confusion, and his enemies at home induced the King of Spain to have him brought home in chains. The revulsion of feeling upon his landing in this shameful plight was instantaneous, and he was restored to freedom and honour. Meanwhile, Da Gama had discovered India, in seeking which Columbus had found America. Columbus made another voyage, and explored more of the coast of America, and returned to die in poverty and obscurity. A quarter of a century later Cortez was in Mexico, and Pizarro was conquering Peru. The pilgrimage to the West had begun.

Comte, Auguste

b. Montpellier, France, January 19, 1798. d. Paris, September 5, 1857.

His full name is Isidore Marie Auguste François Xavier Comte. When twenty years of age, the founder of Positivism became the friend and disciple of Saint-Simon; but they took each his own way after four years, and Comte, unaided, founded the school of thought now known as the Positivists.

Confucius

b. Shantung, China, 551 B.C. d. Shantung, 478 B.C.

The name of the great Chinese philosopher was Kung, and we preserve the Latinised form of that name and the term which his disciples applied—literally Kung the philosopher, or the Master Kung. He was the son of a soldier, whose widow was left to educate the child. The latter, when he grew up, was occupied as keeper of the public supply of grain and of the herds. Later he became a wonderfully successful governor, Minister of Works, and chief magistrate of his native place. The jealousy of a powerful neighbour caused his retirement, and from that time forward he wandered for years, attended by his followers, expounding his philosophy. Some of our best-known maxims were first uttered by Confucius. His memory is worshipped to-day in China by every class of the community from the Royal Family downwards, and each town and village must have its temple consecrated to his memory.

Constantine the Great

b. Naissus, Upper Mesia, 272 A.D. d. Nicomedia, Asia Minor, May 22, 337.

Constantine was the son of Constantius Chlorus, who re-established Roman dominion in Britain and became Augustus. His son is commonly called the first Christian Emperor of Rome. As a fact, Constantine, while making Christianity the form of worship for his subjects, was not wholly a Christian until his end was approaching, when he was baptised. Throughout his life he paid official honour to heathen gods. A great soldier and far-seeing administrator, he made himself, after bloody conflict, master of the western portion of the empire, and, finally, emperor of the whole. Having defeated Licinius near Byzantium, he established his capital there, and in 330 inaugurated it under the name of

Constantinople. It was under his auspices that there assembled the great Church Council of Nicæa, at which was produced the Nicene Creed.

Cook, Captain James
b. Marton, Yorks, October 27, 1728. d. Hawaii, February 14, 1779.

The son of a farm-labourer, Cook ran away to sea, and by the time he was thirty-one had attained the rank of master in the Navy, and was given the task of charting the St. Lawrence and the shores of Newfoundland. His work here, as everywhere else, was marked by remarkable thoroughness. He circumnavigated New Zealand, and in the name of his country took possession of the east coast of Australia; circumnavigated the globe near the Antarctic Circle, and explored the Pacific Ocean. He was killed in a quarrel between members of his party and natives in Hawaii. An intrepid voyageur, Cook was a man of noble character, and so universally respected that orders were issued to all French ships by the French Government, during the war of 1779 between France and England, to treat Cook and his vessels as neutral allies.

Copernicus, Nicolas
b. Thorn, Prussia, February 19, 1473. d. Frauenburg, Prussia, May 24, 1543.

Like so many other illustrious men, the father of modern astronomy was the son of humble parents. It was his good fortune to be mentally equipped not only by diligent personal effort, but by a course of study at Cracow University, where he graduated as doctor of medicine. He taught mathematics, became a canon, busied himself with Church work and lay offices. But all his leisure was devoted to astronomy. The so-called Copernican system remained to be established by great men who followed; but he led the way with a new theory, and braved the terrors of the Church to state the case as it appeared to him.

Corneille, Pierre
b. Rouen, France, June 6, 1606. d. Paris, October 1, 1684.

The greatest tragic dramatist of France turned to writing when the attempt to win success at the Bar had failed. He was for some time one of Cardinal Richelieu's "five poets," but was too independent to write at another man's dictation. Corneille ranks with Descartes as the first to free French thought and language from the restrictions due to Latin and Greek influences.

Correggio, Antonio Allegri da
b. Correggio, Italy, 1494. d. Correggio, March 5, 1534.

This great artist takes his name from Correggio, the town near Modena where he was born. Of his work it has been said: "In facility of handling, in absolute mastery of the difficulties of foreshortening, in the management of light and shade as distributed over vast spaces and affecting multitudes of figures, this great master has no rival." The National Gallery possesses some of his masterpieces.

Cortez, Hernando
b. Medellin, Spain, 1485. d. near Seville, Spain, December 2, 1547.

Cortez conquered Mexico for Spain against the orders of Velazquez, who, having given him the command of a small force, sought to depose him. The soldier hurried forward with fewer than six hundred trained warriors of his own nationality and a handful of friendly Indians, a dozen horses, and as many small guns. He founded Vera Cruz, made allies of the Tlascalans, and marched towards Mexico, the capital. Montezuma, the King, came to meet him. He was made prisoner, and siege laid to the capital. A force sent by Velazquez to recall Cortez now drawing near, Cortez took part of his force, defeated the Spaniards, and made the survivors part of his own army, then marched back to Mexico City, to find that those he had left there had been surrounded. Cortez had to battle against a risen nation, and his little force suffered terribly during the retreat from the city. At Otumba he was surrounded, but won a pitched battle against enormous odds, and, having recruited a large number of Indians, returned to the attack upon Mexico. The siege lasted seventy-five days, for the city did not capitulate until its destruction had been practically completed and its population decimated. Cortez had beaten a nation! Expeditions were sent in various directions, and new territories annexed, but Cortez's enemies at home were still powerful. He returned to Spain, and was honoured by his sovereign; but, though appointed captain-general of the New Spain, as it was called, he was not the civil governor. He lived in splendour for several years in Mexico, but, returning for the last time to Spain, died in neglect and obscurity.

Cowper, William
b. Berkhampstead, Herts, Nov. 15, 1731. d. E. Dereham Norfolk, Ap. 25, 1800.

Genius and madness dominated the life of the author of "The Task." A morbid sensitiveness at school made his life hateful to himself. It made him shrink in terror from the duties which should have been his as Clerk of the Journals of the House of Lords. He repeatedly attempted suicide, and was confined as a lunatic. Afterwards began that intimacy with the Unwins which lasted for many years after the death of Mr. Unwin. Later there came into the life of the poet Lady Austen, who told him the story of John Gilpin, and inspired him to write "The Task." He translated Homer, but not with success, and recurrent dementia sadly marred his life. His poetical writings have had a great influence upon English literature, while his letters are a never-failing delight to the student.

Crompton, Samuel
b. Firwood, Lancs., December 3, 1753. d. near Bolton, Lancs., June 26, 1827.

The inventor of the spinning-mule was the son of a small farmer, and helped his widowed mother in farmwork and weaving. The desire to improve upon the old methods, which let the ends of the yarn so readily break, led to his inventing his famous machine. It gave other men vast fortunes, but he reaped little advantage from it, and died poor and in sorrow, defrauded of his just reward.

Cromwell, Oliver
b. Huntingdon, April 25, 1599. d. London, September 3, 1658.

The Cromwells were of good stock—landed gentry, the backbone of the England of those days. Oliver was educated at Huntingdon Grammar School and Cambridge University, then went to London to study law. He became imbued with the tenets of Puritanism, which did not abate their influence when he went down to Huntingdonshire to live the life of an industrious country gentleman. He was returned to Parliament, and it was in the Long Parliament, when he had turned forty, that he first made himself known as above the level of his fellows. When the war with the King broke out, it was Cromwell who most distinguished himself as a soldier. He had had no previous experience, but he proved himself a born general as great in his sphere as any the world has ever known. He raised the famous Ironsides, who were never defeated—neither in our own islands nor on the Continent—nor were his ships otherwise than victorious. He boasted that he would make the name of Englishman as respected as that of Roman had been, and he justified that saying. England under his rule became the sovereign power of Protestant Europe. Meanwhile, however, there was the terrible civil war raging throughout the length and breadth of the land. Cromwell suppressed this with an iron hand, and, plot upon plot originating with Charles I., he had him executed, and himself declared Lord Protector or Regent, as we should now say. His followers wished him to be crowned king, and had he lived longer he would no doubt have yielded to their wishes. At the same time,

however, he did not wish to wound the susceptibilities of the Republican party, and refused the title. He ruled as Protector for less than five years, and in that time proved himself the greatest and mightiest ruler this land has known. The downfall of the edifice which he had raised followed quickly upon his death, and England submitted to Charles II., with his Court of unexampled corruption, debauchery, and shame.

Crookes, Sir William

b. London, June 17, 1832.

From his earliest childhood he has been deeply interested in science, and when still a youth was appointed assistant to Dr. Hoffman at the Royal College of Chemistry. Before he was thirty, a chance observation, made during a spectroscopic examination, led him to the discovery of a new metal- thallium. His method in dealing with this was characteristic. He spent eight years in investigating its substance and properties and weight. One thing led to another. He found that it must be weighed in a vacuum, and this showed that the metal appeared heavier when cold than when hot. This in turn conducted him to his famous researches concerning the discharge of electricity through highly rarefied gases and his examination of radiant matter, all tending towards investigations concerning radium, with which his later years have been engaged. A practical scientist, he has done great things in promoting pure water supply and in the treatment and disposal of sewage.

Curie, Mme. Marie Sklodowska

b. Warsaw, Poland, November 7, 1867.

The daughter of a Professor of Physics at Warsaw College, Madame Curie, from her earliest childhood, was accustomed to the work in her father's laboratory, and came in time to know as much of chemistry as himself. On going to Paris to complete her education, she met and married M. Pierre Curie (b. Paris, May 15th, 1859), and together they discovered radium, and revolutionised the whole world of modern scientific knowledge. The experiments attended by so vastly-important results were conducted when the young couple were very poor. Since then the whole scientific world has paid them honour.

Curwen, John

b. Heckmondwike, Eng., Nov. 14, 1816. d. Heaton Mersey, Lancs., May 26, '80.

As the man who, by the Tonic Sol-fa system, made it possible for the masses to learn music, Curwen is entitled to a place in the gallery of fame. An Independent minister, he was always interested in teaching, and this led to his being asked, at a conference of Sunday-school teachers, to recommend the best and simplest method of music-teaching. As the result, he gave to the world the system with which his name is associated. The principle of that system he seems first to have acquired from a Miss Glover, daughter of a Norwich clergyman. His later years were entirely devoted to the propagation of this system. He wrote many books upon it, and founded the Tonic Sol-fa College. Millions of people owe their knowledge of music to his efforts.

Cuvier, Georges

b. Montbeliard, France, August 23, 1769. d. Paris, May 13, 1832.

The full name of this most famous of comparative anatomists was Léopold Chrétien Fréderic Dagobert Cuvier that given in the heading was his literary style. He filled many offices in the State, and was an indefatigable worker. The theory of evolution found in him a doughty foeman, but his work in comparative anatomy was of vast importance to the science.

Cyrus the Great

b. about 592 B.C. d. 529 B.C.

As to the birth and death of the founder of the Persian empire, fact is less traceable than legend. He was a great warrior, an enlightened administrator, and a humane conqueror. The scene of his conquests lies in the story of the Old Testament. It was he who, after conquering Babylon, permitted the Jews to return to Egypt to rebuild the temple. He not only permitted them to depart in peace, he restored to them the vessels of the temple which had been carried away by Nebuchadnezzar.

Daguerre, Louis Jacques Mandé

b. Cormeilles, Normandy, November 18, 1789. d. France, July 12, 1851.

Skilled as a painter, Daguerre followed up the discoveries of Nicéphore Niepce in obtaining permanent pictures by the action of sunlight, and with him produced the "Daguerrotype" process, the pioneer of modern photography.

Dalton, John

b. Eaglesfield, Cumberland, September 6, 1766. d. Manchester, July 27, 1844

One of the greatest chemists of any age, Dalton was the son of poor parents, his father, a Quaker, being a weaver. It was his fortune to have within reach a cousin who kept a school, at which he was able to develop his love of science. During his life he held many appointments, enabling him to impart his knowledge to others. But he was himself a student all his days. There was so much for him to learn. It fell to him to demonstrate the atomic theory, and new facts innumerable in connection with gases, steam, acids, and so forth. He and his brother were colour-blind, and first drew attention to the existence of this physical disability, hence its early name Daltonism.

Dante, Durante Alighieri

b. Florence, May, 1265. d. Ravenna, Italy, September 14, 1321.

Of honourable and ancient lineage, Dante was the son of a lawyer, and in his young manhood fought with bravery in the wars in which Florence was engaged. He attained to honourable office as a citizen, and successfully discharged civic functions seemingly incompatible with a temperament such as his. In the struggle of his native state to defeat the plan of the Pope to make Florence simply a dependency of the Papacy, Dante took an active part. He was afterwards sent on a mission to the Pope, and never permitted to return. The faction with which he was allied losing the day, a baseless charge of peculation was preferred against him, sentence of banishment passed, followed later by threat of execution; this latter twice repeated. For many years afterwards he was a wanderer, teacher, and student, acquiring that vast store of knowledge which made him the intellectual phenomenon of his age. Florence, which he so loved, he never saw again. His wanderings ended at Ravenna, and there he died. As to the production of his works, no chronological record exists; nor does that much matter. His "Divine Comedia" is known and loved wherever men have a written language. Dante gave Italy a language and a literature. It has been said, "God created Dante and Italian literature together." He began his great work in Latin, but abandoned the project, as Shelley has said, "to create a language, in itself music and persuasion, out of chaos and inharmonious barbarisms." The Beatrice of his dreams was Beatrice Portinari, whom he met when he was a child of nine, and she a few months younger. His passion for her was idyllic. She was married at the age of twenty, and died four years later; and some years afterwards Dante himself married a Florentine lady, by whom he had several children. She remained in Florence after his banishment; but when, later, sentence of death was passed upon her sons with their father, she joined the poet in exile.

Darwin, Charles Robert

b. Shrewsbury, February 12, 1809. d. Down, Kent, April 19, 1882.

Anticipated to a certain extent by his grandfather Erasmus Darwin, the founder of the

Darwinian theory of evolution, raised the crude hypotheses of others to a verifiable theory. Although he was destined for the Church, he was a "born" biologist, and the happy chance by which he was able to accompany the Beagle on her scientific survey gave him several years in which to collect data as to the flora and fauna of many lands. When afterwards he settled down to country life in England, he was able to turn this knowledge to profitable account in his famous "Origin of Species." He devoted years to the compilation of the work, and, as it was, had to be hastened by his friends into publication by the remarkable discovery that Dr. Alfred Russel Wallace was working along lines similar to his own, to the same goal of discovery. Wallace sent his paper on the subject to Darwin, and the latter was prevailed upon to read, with this, one of his own prepared a year earlier, before the Linnean Society. His theory provoked fierce controversy throughout Europe, but to-day is the scientific gospel of the biologist.

Davy, Sir Humphry

b. Penzance, December 17, 1778. d. Geneva, May 29, 1829.

Countless thousands the perils of whose occupations have been lessened by the use of the safety-lamp in mines—think only of Sir Humphry Davy as the inventor of that mechanism. His contributions to science, however, were many and important. He discovered the use of nitrous oxide, and by previously unknown processes proved the existence of numerous metals potassium, sodium, magnesium, calcium, strontium, and barium. His researches had highly important results upon agriculture, while his noble work was of inestimable value in far advancing the outposts of the scientific knowledge of the period. He was the son of a wood-carver, and began life as a surgeon's apprentice.

Defoe, Daniel

b. London, 1659 (?). d. London, April 26, 1731.

The father of Defoe was a butcher, and lived in the parish of St. Giles, Cripplegate. His son received a sound, middle-class education, which the industry of the youth vastly improved. In business Defoe failed as a hosier and as a potter. In politics he was not more to be applauded. Many of his writings were political; but that by which he will always be remembered is "Robinson Crusoe," a work suggested by the adventures of Alexander Selkirk, a marooned sailor. The story is, of course, the creation of Defoe's own brain, but it is a masterpiece of realism, and of simple yet elegant English.

Democritus

b. Abdera, Thrace, 460 B.C. d. about 357 or 370 B.C.

"The laughing philosopher," as he is called, was a man of noblest mind, stored with all the learning of his age. He travelled to wherever knowledge was to be gained. Fragments of his writings which remain show him to have been another Aristotle. His exposition of the atomic theory has been substantially confirmed in successive eras.

Demosthenes

b. Pæania, Greece, 384 B.C. d. Calauria, Greece, October 12, 322 B.C.

Statesman and patriot, Demosthenes was defrauded while a minor of the greater part of his estate. To recover his possessions, he studied law, and became a lawyer and the greatest orator of all time. His "Philippics" were speeches against the encroachment of Philip of Macedon upon Greece. Philip's attack upon the State of Olynthus called forth the "Olynthiacs" of Demosthenes. Perhaps the greatest triumph of his oratory was when he confronted the ambassadors of Philip, and in a great speech induced them to join with Athens against Philip. Very famous, too, is his speech delivered to clear himself of the charge of peculation. Success crowned the arms of Philip and his great son Alexander; but when the latter was dead, Demosthenes headed another revolt, and, being captured by his enemies, took poison.

Descartes, René

b. La Haye, France, March 31, 1596. d. Stockholm, Sweden, Feb. 11, 1650

The father of modern philosophy was educated by Jesuits, but came to the conclusion that he must forget all he had learnt, and instruct himself from the book of knowledge - the world itself. He became a soldier, and fought in several battles; then travelled far, settling eventually in Holland, where for twenty years he studied and wrote. Finally he returned to Stockholm, where he died. He established philosophy upon a new and surer foundation, and presented an entirely new basis for the study of mathematics.

Dewar, Professor Sir James

b. Kincardine-on-Forth, September 20, 1842.

A chemist of world-wide repute, he is the co-inventor of cordite, and was the first to obtain liquid and solid hydrogen. He has been President of the British Association, and the recipient of innumerable degrees and diplomas.

Diaz, President Porfirio

b. Oaxaca, Mexico, September 15, 1830.

The man who has "made" Mexico was intended by his parents to enter the Church, but he chose the sword, and plied it with deadly effect during those stormy days whicl fo[illegible]d the [illegible]ithdr[illegible] of the French troops. He has twice been taken prisoner when engaged in revolutionary fighting, and had the narrowest escapes of death. But, fighting his way to the Presidency, he has remained there term after term, to suppress the revolt, disorder, bloodshed, and dishonesty which he found, and substitute peace and order, good government, commercial prosperity, and security. He has made Mexico the model nation of South America.

Dickens, Charles

b. near Portsmouth, Feb. 7, 1812. d. Gadshill, near Rochester, June 9, 1870.

"Mr. Micawber" is Dickens's own father, which helps us to realise how the son regarded his parent. He was a thriftless, helpless man, first a clerk in the Navy pay office at Portsmouth, and years afterwards a Parliamentary reporter. The novelist had but a meagre education, but read eagerly all the books upon which he could lay hands. When his father lost his situation at Portsmouth, the family lived in poverty in London, and Dickens was compelled to work in a blacking factory, where, for six shillings a week, he pasted labels on the pots of blacking. From this he passed to a further spell of schooling, then had some experience in a lawyer's office, and finally entered journalism as a reporter of Parliamentary proceedings. Collecting some articles which he had written, he published them in book-form as "Sketches by Boz." This attracted the attention of a writer, who was able to recommend him to Messrs. Chapman & Hall when the latter contemplated starting a serial story to run with the illustrations to be drawn by Seymour, the artist. "Pickwick Papers," which began to appear in 1836, when Dickens was twenty-four, was the result. Success was assured after the first few instalments had appeared. Now fairly launched, he wrote "Oliver Twist," "Nicholas Nickleby," "Master Humphrey's Clock," "The Old Curiosity Shop," and "Barnaby Rudge," in rapid succession. He was famous throughout the English-speaking world by the time he had reached the age of thirty. Thereafter his popularity suffered a temporary decline, and it was because he was in debt that he went to Genoa to finish "Chuzzlewit," and afterwards applied unsuccessfully for the position of stipendiary magistrate in London. Upon the "Daily News" being established, Dickens was appointed editor, but

soon relinquished the post to start a paper of his own. The stage had always an attraction for him, and this, as well as the prospect of great pecuniary gain, had much to do with his undertaking his famous readings. These succeeded beyond his wildest hopes in this country and in America, which latter country he visited for the second time when over fifty. He made great sums by his platform work; but the excitement and strain were too heavy a tax upon his energies, and he died suddenly at Gadshill, the home with which he had fallen in love as a youth, and bought as a man. Dickens's married life was not happy, and he and his wife separated twelve years before his death. They had seven sons and three daughters.

Diderot, Denis

b. Langres, France, October 15, 1713. d. Paris, July 30, 1784.

Diderot's forefathers had for generations been working cutlers, and he, receiving a classical education, was the first to break away from the family habit. His father thereupon discarded him, and he set to work to maintain himself by his pen. He undertook, with D'Alembert, an encyclopædia, and for this gathered about him all the greatest writers of France. But the philosophy of the authors was too revolutionary for the official public taste, and again and again Diderot was in danger of imprisonment. The sale was more than once prohibited, and D'Alembert threw up the work in despair. Diderot continued bravely at his task, though it took him twenty years to complete it. He enriched French literature in many ways, and gave a great impulse to intellectual progress.

Diophantus

Lived about 275 A.D.

The writer of the earliest extant treatise on algebra, Diophantus is not clearly to be traced in any records giving data concerning his birth and death. He lived at Alexandria in the third or fourth century, and wrote three works—"Arithmetics" (six of the thirteen books being extant), "Polygonal Numbers," and "Porisms." Algebra was diligently studied in the great days of the Arabian school of learning, but it is believed that the principles of the science were not known before the day of Diophantus. Even if they were so, however, he vastly enriched it. The famous Hypatia wrote a commentary on his works, but this, unfortunately, is not now in existence.

Disraeli, Benjamin, Lord Beaconsfield

b. London, December 21, 1804. d. London, April 19, 1881.

The son of a Jew, Isaac Disraeli, the distinguished man of letters, Benjamin underwent as a child the peculiar rites which made him a member of the Jewish community, but at the age of twelve was baptised at St. Andrew's, Holborn. Having established a reputation with one or two political novels, he travelled, then returned, to stand for Wycombe as an advanced Radical, but was not elected until 1837, when Maidstone chose him. He was now a Tory, and assiduously courted the favour of Peel, but, not winning the recognition he had expected, turned upon and helped to defeat him. Hitherto regarded as a needy adventurer, he now rapidly rose to power—became Chancellor of the Exchequer, and twice Prime Minister. He carried a democratic Reform Bill, abolished Church patronage in Scotland, bestowed upon the Queen the title Empress of India, did a good stroke for his country in acquiring the Suez Canal shares, and embarked upon an Imperial policy as to the wisdom of which politicians differ. To those of his own party he appeared a man of inspiration, of lofty ambitions, and exalted instincts; to his opponents, an unscrupulous, untruthful man, greedy of power, and prepared by any means to gain it. Disliked and distrusted at first by Queen Victoria, he became in time her most trusted counsellor. She made his wife—a wealthy widow, whom he, when thirty-five, had married when she was fifty-six—a viscountess, and in 1876 conferred upon him an earldom.

Dollond, John

b. London, June 10, 1706. d. London, November 30, 1761.

The inventor of the achromatic telescope was the son of silk weavers, who had fled to England on the revocation of the Edict of Nantes. He learned his parents' trade, and was compelled, by the early death of his father, to forgo any ordinary education. But he denied himself sleep that he might study, and acquired languages and scientific knowledge with extraordinary facility. It was not, however, until he had a grown-up son that he forsook silk-weaving to apply himself practically to optics and invent the telescope, by which he is rendered for ever famous. After his death a curious fact was established. Dollond's discovery had been anticipated by thirty years. Another student had produced an achromatic telescope. This was clearly established in evidence upon trial, but the court held that the Dollonds' rights had been invaded when the earlier instrument was now placed upon the market. Hall, the other inventor, had "confined the discovery to his closet, and the public were not acquainted with it, and Dollond was to be considered the inventor." The lesson from this decision, which still holds good in law, is obvious.

Dryden, John

b. Aldwinkle, Northants, August 9, 1631. d. London, May 1, 1700.

A son of the parsonage, Dryden was first sent to Westminster, then to Cambridge, and entered upon his career as a sturdy Parliamentarian. He became eventually a convert to the Royalist side, and was Poet Laureate and Historiographer Royal, and at fifty-five seceded to the Roman Catholic Church. The sincerity of this conversion, coming with the accession of James II., has been impugned; but it seems to have been one of conviction, for when the Revolution was effected Dryden declined to take the oath, though his refusal cost him all hope of official emolument. He wrote his many plays solely for profit. His critical work, his poems, and his satires, were dearer to his heart, and among the finest works in the language. His translations, too, were admirable. He was a great master of pure English bold, vigorous, original, with a perfect ear for the melody of language—and wrought a revolution in prose and versification.

Dumas, Alexandre

b. Villiers-Cotterets, France, July 24, 1803. d. Puys, France, Dec. 5, 1870.

His father, General Alexandre Davy de la Pailletrie Dumas, was a famous soldier, son of a marquis and a Haytian negress named Dumas. The novelist and playwright had for his mother the daughter of a tavern-keeper. He was first a clerk, but devoted some years to study, with a view to a literary career. Once launched upon the sea of letters, his output was little short of marvellous. "The Three Musketeers," "The Black Tulip," and "Monte Cristo," and other works by which he is rendered famous throughout the world, were only items in an unparalleled flood of books. He was a terrible plagiarist—put his name to other men's work, and is even said to have contemplated issuing as his own story a prose version of part of Homer. He had nearly five score men as collaborators at one time and another during his career. They supplied plots and descriptions, but Dumas put magic into the scenes, and breathed life into the figures.

Edison, Thomas Alva

b. Milan, Ohio, U.S.A., February 11, 1847.

One of the most striking examples of what can be achieved when genius is supported by courage and determination, Edison's career was for years

a struggle against disadvantages. He had little education, and when twelve years of age was turned out to earn his living as a newspaper-seller on a railway. He managed to set up a small printing-press on board a train, and to edit and print, and sell his own paper. In his spare moments he studied chemistry, and persuaded a telegraph-operator to teach him telegraphy. This led to his first invention, the duplex telegraph, by means of which messages can be sent from one wire to another without the aid of the operator. The printing telegraph machine followed, and after that, patent upon patent, the carbon telephone-transmitter, the microtasimeter, the aërophone, the megaphone, the phonograph, the incandescent lamp, and electrical appliances innumerable. The incandescent arc lamp he invented to suit his own wants. He could not get sufficient light to carry out the work upon which he was engaged, and never rested until he had devised his new method of illumination.

Elgar, Sir Edward

b. Broadheath, Worcestershire, June 2, 1857.

The greatest living English composer is an entirely self-taught man. His father was an organist, but Sir Edward cannot remember ever having a music lesson. For twenty years he studied and composed without recognition, but since then he has gained the highest honours in England and on the Continent, and is regarded not merely as the greatest master of English music, but as the foremost composer of the age.

Eliot, George

b. near Nuneaton, Warks, Nov. 22, 1819. d. Chelsea, Dec. 22, 1880.

One of the greatest novelists produced by England, "George Eliot" was in private life Mary Ann Evans, youngest daughter of a carpenter, turned land-agent. She received a sound education, and when her school-days proper were ended had lessons in German, Italian, and music. Her first literary effort was a translation of Strauss's "Leben Jesu," and this brought her in touch with the editor of the "Westminster Review," whom, after she had visited the Continent, she joined as assistant editor. She lived with the Chapmans, and there met all the literary lions of the period. Among them was George Henry Lewes, to whom she was introduced by Herbert Spencer. Lewes was married, but separated from his wife. The friendship of the young people ripened into affection, and they agreed to set convention at defiance. They lived together as man and wife until Lewes died. Her first effort in fiction, undertaken at the suggestion of Lewes, appeared in a magazine, under the pseudonym which she afterwards retained. Its success encouraged her to write "Adam Bede," which won for her an immense triumph. "The Mill on the Floss," "Silas Marner," and "Romola" followed, each gaining for her new laurels, but each making her writing more than ever a matter of anxiety. Towards the close her work suffered from over-elaboration, and too great care. Nevertheless, "Middlemarch" is considered by some her best work, even though one authority declared "Adam Bede" the "finest thing since Shakespeare." She wrote some poems, but it is as a novelist that George Eliot will always be remembered. Two years after the death of Lewes she married his and her old friend, Mr. John Cross, who afterwards wrote her life. She died the same year. Mr. Swinburne has said of her: "In George Eliot it is the most vivid and vital impulse which lends to her large intelligence the utmost it ever has of the spiritual breath and living blood of genius, and never had anyone such gift more plainly and immediately as from the very heart of heaven."

Elizabeth, Queen

b. Greenwich Palace, Sept. 7, 1533. d. Richmond, March 24, 1603.

It was the happy fortune of Queen Elizabeth to be born in an age of great men, an era which knew Shakespeare, and Spenser, Sidney, Raleigh, Howard, Drake, Hawkins, and the illustrious Lord Burghley. With skilful counsellors about her, and valiant men to do her bidding, she, with her "King's heart, the heart of a King of England," as she said, was bound to rank high in the roll of British sovereigns. Her early days were spent in obscurity. The daughter of Henry VIII. by his second wife, she was declared illegitimate. When her half-sister Mary ascended the throne she was subjected to close confinement, being suspected of complicity in Protestant conspiracies. Called eventually to the throne, she took the most important step of her life when she declared for a Protestant England, and refused the hand of Philip of Spain. Mary Queen of Scots was the centre of innumerable plots, and Elizabeth had her imprisoned, and, in the end, executed. This act was made the pretext for invasion by Philip of Spain; and the destruction of "the invincible Armada" was the result. English influence was vastly extended in Europe by Elizabeth, who made her country a world power for the first time. Her reign was distinguished for the advancement of learning, for the extension of commerce and enterprise, and, most of all, of course, for the establishing on a firm basis of the Protestant religion. Personally, Elizabeth was not an ideal character. She was vain and coarse, fickle and revengeful. She was a king in petticoats, but with the weaknesses of a woman of feeble character. Although she was too masterful to admit any special powers in Parliament, she prided herself on basing her rule on the confidence and affection of the people. Deficient in many amiable and moral qualities, she yet proved herself one of the greatest of sovereigns.

Emerson, Ralph Waldo

b. Boston, Mass., May 25, 1803. d. Concord, Mass., April 27, 1882.

"The Buddha of the West," as a distinguished admirer has called him, was for a few years a Unitarian minister at Boston. The views of his congregation not according with his own, he quitted the pulpit, to be henceforth known as lecturer, essayist, and poet. His works, which are as widely read in the Old World as the New, are an unfailing inspiration to the thoughtful. He was an idealist, an invincible optimist, and in religion a rationalist. Twice he visited England, and on the second occasion delivered a notable series of lectures on "Representative Men." His friendship with Carlyle dates from his first arrival in England. Emerson was twice married.

Empedocles

b. Agrigentum, Sicily, 500 B.C. d. Sicily, about 430 B.C.

Sufficient is now known of the life of this famous Sicilian philosopher and physician to dispose of the story that he threw himself into the crater of Etna. His fame and liberality were such that the people wished to make him king. This offer he declined, and established instead a democracy. His philosophy embodied the belief that the world was evolved from fire, air, water, and earth, and that the reverse process of dissolution proceeded under the varying struggle between forces termed affinity and antipathy.

Encke, Johann Franz

b. Hamburg, Germany, Sept. 23, 1791. d. Spandau, Prussia, Aug. 26, 1865.

Famed for his investigations as to the comet now named after him, Encke, who was a soldier before turning to astronomy, solved the problem of the sun's distance. He studied at Göttingen, and was successively astronomer at Seeberg and director of the Berlin Observatory.

Ennius, Quintus

b. Rudiæ, Calabria, 239 B.C. d. Rome, 169 B.C.

He was the pioneer of literature representative of Rome. A soldier, he returned from the wars under the patronage of Cato the Elder, through whose influence Ennius, believed to be of Greek extraction, was made a Roman citizen. He taught Greek, and wrote in almost every style of poetry. His work first gave to Latin literature a character of serious elevation.

Erasmus, Desiderius

b. Rotterdam, Holland, Oct. 28, 1466. d. Basel, Switzerland, July 12, 1536.

The father of Erasmus was the hero of Charles Reade's "Cloister and the Hearth," and the philosopher's real name was Gerrit Gerritszoon. The two terms which he adopted—the first Greek, the second Latin—have the same meaning—"the desired, lovable." During his father's lifetime Erasmus was well cared for, and learned Greek, but afterwards he was defrauded of his inheritance and forced into a monastery. His scholarship won him the patronage of the Bishop of Cambrai, who enabled him to study in Paris. Thereafter he travelled throughout Europe, was released from his monastic vow, and for some years held a professorship at Cambridge University. He was forty-nine when his great work—the first edition of the New Testament in Greek—was published. His original writings, wise and witty, came afterwards. Although he exposed the abuses of the Catholic Church, he would not take any share in the Reformation, and would have been made a cardinal had not death prevented it.

Ericcson, John

b. Vermland, Sweden, July 31, 1803 d. New York, March 8, 1889

A born inventor, who before he was nine had constructed a working model of a water-power sawmill, Ericcson was compelled to waste several years of his life in the Swedish army. All his leisure was devoted to planning mechanical contrivances, and upon coming to England he built a steam-engine to compete against Stephenson's famous "Rocket." Ericcson's ideas were ahead of the times. His steam fire-engine was rendered a failure by popular prejudice and ignorance; while the story of his efforts to induce the Admiralty to test his screw propeller for steamships is historic. He designed the first vessel driven in this manner across the Atlantic, and himself took up his residence in America, where the reception of his schemes was scarcely more friendly than had been the case in England. In spite of all obstacles, he completely revolutionised marine navigation and the building of warships. From his schemes endless achievements have resulted, while the inventions which he carried to perfection serve still as finger-posts for others' guidance.

Euclid

b. Alexandria, about 300 B.C. d. Alexandria, date unknown.

Beyond the fact that he flourished in Alexandria under the first of the Ptolemies, about 300 B.C., dates as to the career of this famous mathematician are not available. It is believed that he founded the great mathematical school of Alexandria, so performing a service of prime importance to the cause of exact science. His chief work extant is the "Elements," which to this day continues the textbook for elementary geometry in the United Kingdom. He did not invent the system to which his name is given. He compiled, arranged, and permanently recorded known mathematical truths.

Euripides

b. Salamis, Greece, 480 B.C. d. Macedonia, 406 B.C.

The last of the Greek tragedians, and the model upon whose style the modern French and Italian drama is fashioned, was born when heroic history was being made by Greece. He did not catch the martial spirit of the age, but passed his youth in study, he became a poet, philosopher, and dramatist of infinite power and passion, and of inexhaustible love for the weak and suffering. Of his eighty plays, eighteen are preserved.

Eyck, Jan Van

b. Maaseyck, Prussia, about 1390. d. Bruges, Flanders, July 9, 1440.

With his brother Hubert—who was twenty years his senior, and died in 1426—he first perfected the system of mixing colours with oils for painting. The brothers painted together as a rule. Their greatest work—the altar-piece for the cathedral at Ghent—was one of their joint efforts. In the National Gallery, London, are fine examples of Jan's individual work.

Fahrenheit, Gabriel Daniel

b. Dantzic, Prussia, May 14, 1686. d. Holland, Sept. 16, 1736.

He was the first to substitute mercury for spirits of wine in the thermometer. The thermometric scale to which he gave his name he fixed as follows: Zero was the lowest temperature observed by him at Dantzic during the winter of 1709; the space between this point and that to which the mercury rose at the temperature of boiling water he divided into 212 parts. He was an F.R.S. of England, and had some celebrity as a practical engineer.

Faraday, Michael

b. London, Sept. 22, 1791. d. Hampton Court, Aug. 25, 1867.

Newington Butts was the birthplace of Faraday; a blacksmith, his father. He received but a scanty schooling, and owed to an accident his chance of winning success in life. He was apprenticed to a bookbinder, one of whose customers, attracted by the intelligence of the apprentice, gave him four tickets for Sir Humphry Davy's lectures at the Royal Institution. Of this opening Faraday took such advantage that Davy, reading his notes on the lectures, appointed him his assistant and amanuensis, and took him for a tour on the Continent. Later, Faraday was appointed professor of chemistry at the Royal Institution, and for the rest of his days devoted himself to scientific research. His discoveries covered the whole field of magnetism, diamagnetism, electromagnetism, and electricity proper. He elucidated the application of induced electricity to lighthouses, the firing of mines, telegraphy, and the magnetic currents of the earth. Within the space at command it is impossible even to indicate the number and scope of his discoveries of first importance. His lectures were famous, his writings models of lucidity and pure English. Few great men have received a more slender educational equipment, but none has eclipsed the importance and varied character of his investigations.

Fawcett, Henry

b. Salisbury, Aug. 26, 1833. d. Cambridge, Nov. 6, 1884.

Fawcett's life-story is another exemplification of the fact that will is greater than physical faculties. He was blinded when a youth by a shot from his father's rifle, but bravely bore his handicap, became a member of Parliament, and as Postmaster-General gave us the parcel post, postal orders, and the sixpenny telegram.

Ferguson, James

b. Keith, Banffshire, April 25, 1710. d. London, Nov. 17, 1776.

The man who, by his lectures and writings, and still more by his mechanical appliances, did much to popularise astronomy in England, was almost wholly self-taught. He learned to read from hearing his father teaching his brother. He gained his first idea of mechanics by seeing his father plying the lever. While working as a shepherd boy he made models of mills and other machines, and at night studied the stars, and planned the heavens with beads strung upon threads. For some years he was able to maintain his family by painting miniature portraits.

Fichte, Johann Gottlieb
b. Rammenau, Germany, May 19, 1762. d. Berlin, Jan. 27, 1814.

A son of poor parents, Fichte lacked the means to qualify for the Church, so took service as a tutor until he could afford to devote himself wholeheartedly to the teaching of Kant. He published an essay which was mistaken as being from the pen of that philosopher, and this proved the making of the younger man's reputation. He was appointed professor of philosophy at Jena, and there remained until he was falsely charged with Atheism. He removed to Berlin, where he lectured and wrote. Napoleon's great victories over the Germans called forth Fichte's famous Addresses to the German nation, in which he pointed out that the true way to national regeneration lay in a system of public education. After the war Fichte was invited by the king to draw up a constitution for a new university, and became its first rector. He died of fever, contracted through nursing his wife, who had herself taken it while tending the wounded German soldiers, of which the Berlin hospitals were full.

Fielding, H nry
b. Glastonbury, Somerset, April 22, 1707. d. Lisbon, Oct. 8, 1754

"The father of the English novel" was the son of a general, and half brother of Sir John Fielding, the famous blind magistrate of Bow Street. He became a theatre proprietor, but his bold attack upon the ministry of the day led to his being driven out of this venture. He was called to the Bar, but turned to literature, to write the novels which have made him immortal.

Finsen, Niels Ryberg
b. Faroe Islands, Denmark, 1861. d. Copenhagen, Sept. 24, 1904.

Crowned by the discovery of the application of light to the cure of disease, Finsen's career was one long battle against disease. Twenty years before the end came he knew that he was a doomed man, yet sought the physical salvation of others, though he knew that his own life was ebbing away. His famous light cure for lupus was first made popularly known in England through the wisdom and goodness of Queen Alexandra.

Flaxman, John
b. York, July 6, 1755 d. London, Dec. 7, 1826.

Destined to rank at the head of English sculptors for inventive power, controlled by unerring sense of beauty, Flaxman was the son of people in the poorest circumstances. He himself was seriously deformed. His genius discovered itself when he was engaged by the Wedgwoods to draw designs for their pottery. He taught himself Latin and Greek enough to enable him to read the poets, and spent seven years in Italy, where he executed numerous classical groups and drew illustrations for Homer. From his return to England to the end of his days he was engaged upon monumental sculpture, though he found time to discharge the duties of professor of sculpture to the Royal Academy.

Fo-Hi
flourished about 2400 B.C. d. Chiu-Choo.

China gets her political and social system from Fo-Hi, who is supposed to have lived in the twenty-fourth century before the Christian era. Marriage, the division of time and of seasons, the calendar, the use of metals and minerals, of building, fishing, and hunting, are among the institutions said to have been originated by this representative of the founders of the oldest known civilisation

Fox, Charles James
b. London, Jan. 24, 1749. d. Chiswick, Middlesex, Sept. 13, 1806.

"The greatest debater the world ever saw" was Burke's description of Fox. He was the third son of the first Lord Holland. In Parliament he opposed the coercion of our American colonists and the war with France. Although George III. cordially disliked him, he was twice Foreign Secretary. He was engaged upon a bill for the abolition of slavery when laid low by death. Fox's private life was deplorable.

Fox, George
b. Fenny Drayton, Leicestershire, July 1624. d. London, Jan. 13, 1691.

The founder of the Society of Friends, or Quakers, was a worthy itinerary preacher who, the son of a weaver, served an apprenticeship to bootmaking. His outspoken denunciation of forms of worship of which he did not approve caused him to be the victim of repeated persecution and imprisonment. But he made converts wherever he appeared, and they suffered with him. During the latter part of his career he was accompanied by Penn, and visited, among other places, America and Holland.

Francis, St., of Assisi
b. Assisi, Italy, 1182. d. Assisi, Italy, Oct. 4, 1226.

His surname was Bernardone. A serious illness turned him from a life of profligacy to that of an ascetic, vowed to chastity and poverty. He gathered about him others who subscribed to the conditions, and founded the famous Franciscan brotherhood. After a visit to Egypt, where he preached before the Sultan, and obtained for his order the guardianship of the Holy Sepulchre, he retired to a hermit's cell, where tradition alleges he received upon his own person the wounds of the Saviour. He was canonised two years after death.

Franklin, Benjamin
b. Boston, Mass., Jan. 17, 1706 d. Philadelphia, April 17, 1790.

The man who, by a novel experiment, was to discover that lightning and electricity are identical, to establish the distinction between positive and negative electricity, and achieve other scientific triumphs, began his career as a "printer's devil" in the newspaper office of one of his brothers. His life was amazingly active. He set up a press of his own in Philadelphia after having worked for eighteen months in a London printing-office, published with unprecedented success "Poor Richard's Almanack," returned to England on a diplomatic mission, and was honoured by scientific bodies and both Universities. While carrying on his business as a newspaper proprietor he discharged more or less important offices under Government, and at the same time conducted scientific investigations as to tides, meteorology, and colours. Prior to the War of Independence he came again to England, in the hope of securing the rights of his fellow colonists. Failing, he returned, took an active part in preparing the Declaration of Independence, then proceeded to Paris, and negotiated a treaty whereby France recognised the new Republic and lent armed assistance. Eventually he opened a correspondence with England which paved the way to peace. Thereafter he was American Ambassador to France, and subsequently filled various offices at home. One of the most completely successful men of any age in all the branches of activity in which he engaged. Franklin left behind him writings which to this day continue to be read by every nation which has a written language.

Franklin, Sir John
b. Spilsby, Lincs., April 16, 1786. d. King William's Land, June 11, 1847.

He discovered the North-west Passage, but died, probably starved to death, in the scene of his triumph. After serving at the Battle of Copenhagen and at Trafalgar, and mapping parts of the coast of Australia, he twice commanded Arctic exploring expeditions, and received honourable reward for successes gained. For seven years he was governor of Van Diemen's Land (Tasmania). On May 18th, 1845, he sailed in command of the two

Government ships Erebus and Terror, and never returned. In the twelve years following his departure thirty-nine relief expeditions were sent out by England and America. The last—one of five despatched by his widow—discovered all that there was to be learned. The party had suffered frightful privations, and had all died. A memorandum was found giving the date of Sir John's death. Some of the victims had resorted to cannibalism in their agony of starvation.

Fraunhofer, Joseph von

b. Straubing, Bavaria, March 6, 1787. d. Munich, June 7, 1826.

A skilled optician, who did much to improve the telescope and other optical instruments, he is chiefly famous as the discoverer of the dark lines in the sun's spectrum, named, in his honour, "Fraunhofer's lines."

Frederick II., The Great

b. Berlin, Jan. 24, 1712. d. Sans Souci, Potsdam, Aug. 17, 1786.

When Frederick came to the throne of Prussia, Germany was loosely ruled by some three hundred men of different titles. There was no cohesion or national spirit, so when the Emperor Charles VI. of Germany died, and the validity of his daughter's succession was impugned, Frederick determined to take Silesia, part of which had anciently belonged to Prussia. The number of his people was inconsiderable—only half that of London—but he had a highly-organised army of eighty thousand men and a well-filled treasury. He was everywhere successful, and added Silesia to his own dominions. An alliance which he had concluded with France and Bavaria was now terminated, but he was afterwards forced to renew this and to enter upon a second war. His third and last war was the greatest and most terrible. Allied against him were France, Austria, and Russia, an unparalleled combination. England had been helping him with subsidies, but this source of revenue was stopped. What would have happened had not the Empress of Russia died, and the course of events been thus unexpectedly altered, it is difficult to imagine. He had fought with magnificent skill and courage, but the odds had become overwhelming. Still, he had not allowed his country to incur one penny of debt, though the land had been reduced almost to starvation. The latter part of his reign was spent in peace. He added a part of Polish Prussia to his dominions, and he retained Silesia. For the rest, he was happiest when promoting the educational and material interests of his people. He loved literature and the arts. He was a friend of Voltaire, and had him for some time at Berlin. Frederick deserved the appellation "The Great." Had not his time been so much occupied with wars, he would have proved a still greater man.

Froissart, Jean

b. Valenciennes, France, 1337. d. Chimay, Belgium, about 1410.

The chronicler of the knightly doings in Court and camp of the fourteenth century was the son of a Flemish painter of armorial pictures. Showing aptitude for poetry, he attained Court favour and a recommendation to the English Court, where he was patronised by the Queen of Edward III. Thus favoured, he made tours throughout this country, and afterwards in France, Germany, Italy, and Spain, and collected also details as to Hungary and the Balkan Peninsula. His influential introductions and his own pleasant bearing and address served to bring him tales of chivalry, and of more serious affairs wherever dames and knights or squires assembled. He gives us a delightful picture of the Europe he knew from the third decade to the end of the last of the fourteenth century. His poems and romances have merit, but the "Chronicles" are for all time.

Fuller, Thomas

b. Aldwinkle, Northants, June, 1608. d. London, Aug. 16, 1661.

This witty divine and historian was a son of the rectory, and as a youth imbibed principles which made him all his life a sturdy Royalist. He suffered for his loyalty, but made good his losses at the Restoration. Of his writings, the most famous is his "English Worthies," a posthumous publication, to which he had devoted twenty years' work. It is one of the great classics of the language. "A tithe of his beauties," says Coleridge, speaking of his style, "would be sold cheap for a whole library of our classical writers, from Addison to Johnson, and Junius inclusive."

Fulton Robert

b. Little Britain, Pa., 1765. d. New York, Feb. 24, 1815.

Born of Irish parents, Fulton came to London to study portrait painting, but after some years devoted himself wholly to engineering, and was the first successfully to apply steam to navigation. He had many disappointments with other inventions, prejudice and ignorance being in alliance against him.

Gabelentz, Hans Conon von der

b. Altenburg, Germany, Oct. 13, 1807. d. Triptis, Germany, Sept. 3, 1874.

One of the most gifted of philologists, he was master of eighty languages. He wrote upon tongues of which previously little had been known. His son, who outlived him only nineteen years, was an accomplished Orientalist.

Gainsborough, Thomas

b. Sudbury, Suffolk, May, 1727. d. London, Aug. 2, 1788

In the estimation of Ruskin, Gainsborough was the greatest colourist since Rubens. The son of a wool manufacturer, he showed from the earliest age a gift for sketching, and when fourteen was sent to London to study. Four years later he returned to his native place, married a lady with means, and set up a studio as a portrait painter—first at Ipswich, then at Bath. There he remained for fourteen years, painting many fine portraits. Removing to London, he became one of the founders of the Royal Academy, from which he withdrew four years before his death, annoyed at the position awarded to his picture, "The King's Daughters." His works numbered upwards of three hundred, of which more than two-thirds were portraits. Gainsborough was a man of impetuous temperament, but on the whole singularly lovable, musical, sociable, generous, loyal.

Galen, or Claudius Galenus

b. Pergamos, Asia Minor, 131 A.D. d. Sicily (?), about 200 A.D.

This celebrated Greek physician and philosopher revived the old systematic study of medicine and surgery, and enriched it with independent research of inestimable value. He was the standard authority and fount of learning to whom students turned for the next twelve centuries. He travelled far in quest of knowledge, but was driven from Rome by the jealousy of the physicians there. Of his treatises, some four score remain to us—valueless now in the light of modern knowledge, but wonderful records of the industry and talent of a man vastly ahead of his time.

Galileo

b. Pisa, Italy, Feb. 15, 1564. d. Arcetri, Florence, Jan. 8, 1642

Galileo Galilei, the father of physics, was descended from a noble but impoverished Florentine family, originally named Bonajuti. As a child he displayed versatile genius in music, in modelling, in painting, and in mechanics. While in his youth he invented the first instrument ever devised for accurately observing phenomena in a living organism—a pendulum for recording the speed of the pulse. After studying at Pisa University, he constructed a thermometer, improved the telescope, and turned it for the first time towards the heavens, with the result that he discovered the satellites of Jupiter, proved the

existence of sun-spots, and became persuaded of the truth of the Copernican theory. He carried the subject much farther, and, the attention of the theologists thus drawn afresh to the matter, the works of Copernicus were placed on the "Index Expurgatorius," and Galileo compelled to vow that he would not defend their teaching. Some years later his own "Dialogues of the Two Systems" was published. Thereupon he was summoned to Rome, and compelled, under threat of death or torture, to sign a formal abjuration of the Copernican doctrine. He yielded, and did not suffer the torture commonly believed to have been his fate. But his activities were not checked. He worked on, even when sight failed him, preparing the way for Newton and the other giants who were to follow.

Gall, Franz Joseph
b. Tiefenbronn, Baden, March 9, 1758. d. near Paris, Aug. 22, 1828.

He is commonly called the founder of phrenology. He never used the latter word; his disciples, who are said to have resembled him only in his mistakes, coined it. Their master did not make conformation of the skull the foundation of his system. The functions of the brain itself were his study. He was the son of a physician, and was prohibited from lecturing in Vienna on his theories, on the ground that they were subversive of religion. He lectured through a great part of Europe, and became famous as a physician in Paris, where his closing years were passed.

Galton, Francis
b. Birmingham, 1822.

A grandson of Erasmus Darwin, and cousin of Charles Darwin, he has gained distinction as explorer and philosopher. His researches have done much to advance the knowledge as to heredity. Latterly he has rendered a public service by investigations of finger-prints. His calculations go to prove that the chances against the impressions made by two different fingers resembling each other are one to 64,000,000,000. He thus places at the disposal of the authorities a potent means for the detection of criminals.

Galvani, Luigi
b. Bologna, Italy, Sept. 9, 1737 d. Bologna, Dec. 4, 1798

A noted physician and physicist at Bologna, he conducted experiments with metals placed in contact with the muscles of dead frogs, and came to the conclusion that electricity or magnetism was an animal product. He was wrong, of course; but he has an important place in the story of knowledge, inasmuch as it was his experiments which gave Volta a clue to the important solutions at which he was able to arrive. Galvanism takes its name from Galvani.

Gama, Vasco da
b. Sines, Portugal, about 1460. d. Cochin, India, Dec. 24, 1524.

Charged by his sovereign with the duty of finding a sea route by way of the Cape to India, Da Gama valiantly discharged his mission, established a Portuguese station at Calicut, Malabar, and returned. A succeeding mission was massacred, and Da Gama led a punitive expedition in consequence, and afterwards went out as Viceroy. His work was destined enormously to enrich Europe, and England in particular.

Garibaldi, Giuseppe
b. Nice, Italy, July 4, 1807. d. Caprera, Italy, June 2, 1882.

The son of a seafaring man, and educated for the Church, Garibaldi preferred the sea, became involved in the Young Italy movement, was sentenced to death, but escaped to South America, where he fought in more than one revolutionary war. His return to Italy was followed by another flight to America, where he followed the trade of a candle-maker. This occupation gave place to that of a farmer on the Island of Caprera, near Sardinia, which, by the generosity of English admirers, was, later in his life, made his own property. From this point, until the liberation of Italy was consummated, his days were given to fighting for the freedom of his native land. He was a born leader of guerilla troops, but not gifted in statesmanship, and his career included many mistakes, for which he paid dearly. But he was a sincere, unselfish patriot, and in England was treated as a hero.

Gay-Lussac, Joseph Louis
b. St. Leonard le Noblat, Haute-Vienne, 1778. d. Paris, May 9, 1850.

Distinguished as physician and chemist, he is renowned for his researches on chemical combinations, the results of which were highly important to commerce. He made the discovery of the law of volumes, and was the first man to make a balloon ascent for scientific purposes.

Ged, William
b. Edinburgh, 1690. d. Leith (?), Oct. 19, 1749.

The man who first invented stereotyping, a highly important advance upon the original method of printing from the old movable types, had all his life to fight ignorance, prejudice, and jealousy. These won the day, and, in spite of the manifestly valuable character of his work, he died broken-hearted and in abject poverty.

Gibbon, Edward
b. Putney, April 27, 1737. d. London, Jan. 16, 1794.

"It was at Rome, on the 15th of October, 1764, as I sat musing among the ruins of the Capitol, while the barefooted friars were singing vespers in the temple of Jupiter, that the idea of writing the decline and fall of the city first started into my mind." So came the inspiration for our greatest work in history, "The Decline and Fall of the Roman Empire." A work of such magnitude and splendour could hardly have been expected of the man. He had had little regular scholastic training, owing to ill-health. His stay at Oxford resulted in his conversion to Roman Catholicism. This caused his father, a man of comfortable circumstances, to send him for five years to Lausanne, where the judicious handling of a Calvinistic tutor brought him back to his first faith. Here Gibbon read prodigiously, and remembered what he read, and stored up the knowledge which was to serve him for his great work. He had a love affair here, of which the heroine was to become the wife of M. Necker, and mother of the famous Madame de Staël. Upon the death of his father, he sat for some years in Parliament, but never addressed the House, and though he was granted a sinecure office it lasted but three years. The preparation of his first volume of the history occupied him many years. The others were written with striking rapidity, and the last was published six years before his death, which occurred following his return from Lausanne, where he had lived since 1783, and where nearly half his book was written. Except an autobiography, he wrote little worth mentioning beyond the history, but that amply sufficed to give him immortality.

Giotto, di Bondone
b. near Florence, 1276. d. Florence, Jan. 8, 1337.

His genius for art betrayed itself while he was a boy tending sheep. A generous patron, seeing him sketching upon a stone, had him properly instructed, and he became the head of a famous Florentine school of painting. Many fine specimens of his work remain. He designed the Campanile at Florence.

Gladstone, William Ewart
b. Liverpool, Dec. 29, 1809. d. Hawarden, May 19, 1898

The fourth son of Sir John Gladstone, Bart., a Liverpool merchant of Scottish descent, he was educated at Eton and Oxford, and entered Parliament, representing Newark as "a rising hope of the stern, unbending Tories," as Macaulay said

He held minor offices under Peel in the Administrations of 1834 and 1841, and though he was out of Parliament when the Corn Laws were abolished, he had a great share in preparing the measure which Peel passed. From this time he gradually drifted away from Tory traditions; and after he had raised the questions as to the condition of Greece and of the Neapolitan prisons, a speech of his caused the rejection of Disraeli's Budget of 1852. This led to Gladstone's being made Chancellor of the Exchequer in the Coalition Government which followed. Now and later he showed that genius for finance which made him the greatest Chancellor of our own day. He abolished many vexatious taxes, among them that on paper. Over the Crimean War and the Civil War in America his attitude excited criticism, and he lost his seat at Oxford University, for which he had sat eighteen years. South Lancashire elected him, and, Palmerston dying, Gladstone became Leader of the House of Commons and Chancellor of the Exchequer. His Franchise Bill unexpectedly caused the overthrow of his party, which, however, at the next General Election, gained a great majority, and made him Prime Minister. To take his seat, he had to be elected for Greenwich, South Lancashire having rejected him. The Irish Church was disestablished, the Education Bill of 1870 passed, and the Ballot Bill made law. The elections of 1874 were adverse to Gladstone, and Disraeli became Premier, whereupon the Liberal leader retired temporarily into private life, to be recalled by the Bulgarian massacres and his complete disagreement with Disraeli's foreign and domestic policy. Midlothian returned him as its member in March, 1880, and for that division he sat until the end. He again took office as Premier, and five very troubled years followed. Crime in Ireland, the Bradlaugh incident, affairs in Egypt and the Soudan, and the whole foreign policy of the Government, tended to make the period one of the most exciting and exacting of the century. Again the verdict at the polls was in his favour, but his Government lasted only a brief time, Home Rule causing a serious cleavage, and sending the Liberal party into exile for the next six years. In 1892 the country for the last time gave Gladstone a majority, and he passed his Home Rule Bill through the Commons for the House of Lords to reject it. Then he retired, compelled by failing sight and hearing to withdraw from the scene in which for over three score years he had been a principal and splendid figure. He was a man of intense enthusiasms, lofty ideals, untiring industry, one of the greatest orators and debaters this country has produced, and a writer of the first rank upon poetry and classical and theological subjects.

Gluck, Christoph Willibald

b. Weidenwang, Bavaria, July 2, 1714. d. Vienna, Nov. 15, 1787.

He was the son of a forest keeper in a princely household, and from his cradle showed musical talent. After study and teaching at Prague, Vienna, and Milan, he came to London, as composer of operas for the Haymarket. Here he was enabled to study Handel, and this led to his reaching his highest work. Returning to Vienna, he became the music-master of Marie Antoinette, who materially assisted him in the production of the operas which have made him famous wherever music is sung or played.

Goethe, Johann Wolfgang

b. Frankfort-on-the-Main, Aug. 28, 1749. d. Weimar, March 22, 1832.

Another example of a career turning out differently from parents' designs, Goethe was intended by his father to follow the law, and did actually practise, but literature had always the stronger appeal. A love affair--one of many which are reflected in his poems--inspired the first production, a little pastoral drama. Once begun, there was no end to the flow. Poems, plays, scientific and philosophical writings, even novels, streamed from his fertile brain. In 1775 he was invited by the young Duke Karl August to make his home at Weimar, and there he lived to the end of his days, except when he accompanied his patron, who went forth to fight the French. Goethe was an able statesman, and performed service of note for Weimar. One of his many love affairs led to an association with a beautiful girl of humble birth, whom he eventually married.

Goldsmith, Oliver

b. Pallas, Ireland, Nov. 10, 1728. d. London, April 4, 1774.

Good results have seldom been won from more unpromising material than in Goldsmith's case. The son of an Irish curate, he spent his youth unworthily. With no sense of the value of money, he gambled away the little which should have carried him to America, ran away from college, was rejected on seeking to take Orders, continued his dissipation in Edinburgh and on the Continent, and reached London well-nigh penniless. Here he passed a wretched existence as chemist's assistant, as hack-writer and proof-reader, and as usher. Better times dawned with the production of his essay on the condition of learning in Europe—written to raise funds to enable him to leave the country. Thought of emigration abandoned, he wrote, sandwiched between hack-work, his delightful poems, his immortal novel "The Vicar of Wakefield," and his drama "She Stoops to Conquer." He was improvident to the last, and died owing two thousand pounds. A genius of a high order, he was erratic and unstable.

Gounod, Charles François

b. Paris, June 17, 1818. d. St. Cloud, Oct. 18, 1893.

Son of a painter of no little ability, his talent for music early asserted itself, enabling him to carry off the Grand Prix de Rome before he was twenty-one. His stay in Rome gave him an insight into sacred music, which was to serve him later in life. When he returned to Paris, he tried in vain to find a publisher for some songs which he had written, so accepted a post as church organist, and made up his mind to take Orders. Instead of carrying out this plan, he was persuaded to write an opera. "Sappho" was the result, satisfactory if not brilliant. No commanding success was won until he took Goethe's "Faust" for a subject. That proved the greatest success in French music of the latter half of the nineteenth century. "Romeo and Juliet," his next best work, appealed as strongly to him, but he felt older when he wrote this. The Franco-Prussian War drove him to London, where he wrote a composition for the opening of the Albert Hall, and some songs, of which "Maid of Athens" is best known. Upon his return to Paris he composed operas, and then turned to sacred music. "The Redemption," dedicated to Queen Victoria, is the effort in this direction most esteemed in this country. He was a man of tireless activity, with innumerable works to his credit, but he will be best remembered by those mentioned.

Gray, Elisha

b. Barnesville, Ohio, Aug. 2, 1835.

No history of the telephone is complete which fails to place the name of Gray in the forefront. He claims, indeed, to be the inventor of the instrument. His title to fame, however, does not rest on ground so well occupied, for he has taken out scores of patents in relation to electrical appliances mainly concerned with telegraphy and telephony.

Gray, Thomas

b. London, Dec. 26, 1716. d. Cambridge, July 30, 1771.

Associated as a boy at Eton with Horace Walpole, he accompanied the latter on the "grand tour," but quarrelled and parted from him, and

went to Cambridge, and there had his residence, except for holidays spent with his mother at Stoke Pogos. After refusing the Poet Laureateship, he became professor of modern history at Cambridge. His best-loved poem is the "Elegy Written in a Country Churchyard," one of the most perfect gems in the language; next, the "Ode on a Distant Prospect of Eton College." His most ambitious work is "Progress of Poesy," a noble composition. He lived a life of quiet days, was never married, and was one of the most painstaking poets of any time.

Green, John Richard
b. Oxford, Dec. 12, 1837. d. Mentone, March 7, 1883.
Readers of "Robert Elsmere" will recognise Green in the hero of that novel. He was educated at Oxford, and entered the Church of England, but—partly through ill-health, partly through failing sympathy with its doctrines—he relinquished his association with the Church, and devoted himself to literature. His "Short History of the English People" had an unprecedented success, and is the introduction of practically all students into the history of our country. This, like his larger schemes, was written while he suffered terribly from ill-health. He was greatly beloved by a wide circle of friends, and the story of his long battle against suffering and incurable disease is an object-lesson by which all may profit.

Gregory XIII.
b. Bologna, Italy, Feb. 7, 1502. d. Rome, April 10, 1585.
He was a professor of law for many years before distinguishing himself as one of the theologians at the Council of Trent. Elected Pope when seventy years of age, he made his pontificate memorable by imposing upon Catholic Europe the Gregorian calendar. No revision having been made since the days of Julius Cæsar, there had arisen a discrepancy of ten days. He caused ten days to be eliminated from the month of October, 1582, and modified the plan as to leap years. It took nearly two centuries to get the reform accepted in England, but in the end there was no alternative to the adoption of the Gregorian calendar. Gregory was an enlightened Pope, and spent an enormous sum of money in promoting education. The one blot upon his career was his ordering a "Te Deum" in Rome upon the occasion of the St. Bartholomew massacres. That, however, may have been the outcome of the massacres being represented to him as the suppression of a Huguenot plot and rising.

Gresham, Sir Thomas
b. London, about 1519. d. London, Nov. 21, 1579.
The son of a prosperous Norfolk merchant, Gresham made a fortune in financial operations, and displayed such unselfish patriotism as to effect a salutary influence for good upon the national credit. Towards the end of his life he founded the Royal Exchange, Gresham College, and a number of almshouses.

Grimm, Jacob Ludwig Karl
b. Hanau, Germany, Jan. 4, 1785. d. Berlin, Sept. 20, 1863.
It is as part-author, with his brother Wilhelm, of the delightful fairy stories for children that Jacob Grimm is famous throughout Christendom; but his reputation is based upon higher ground. He was one of the most accomplished philologists ever produced by Germany, and his great dictionary and German grammar are among the most notable of that class of work in existence. He is the father of comparative Germanic philology. Like his brother, he studied law at Marburg, and together they shared the duties of librarian to their patron, the King of Westphalia, and simultaneously filled professorial chairs at Göttingen.

Grote, George
b. Beckenham, Kent, Nov. 17, 1794. d. London, June 18, 1871.
The author of the monumental history of Greece spent thirty-two years of his life in the bank which his grandfather had founded, and of which he eventually became the head. He sat for some years in Parliament, and was an earnest advocate of electoral reform. In addition to the famous history, he wrote an exhaustive work on "Plato and the Other Companions of Socrates," and was engaged up to the time of his death upon a volume on "Aristotle."

Grotius, Hugo
b. Delft, Holland, April 10, 1583. d. Rostock, Germany, Aug. 28, 1645.
From his youth up a diligent student of law, Grotius was early initiated into diplomacy, and turned his attention to the study of International law, of which he may be said to have been the father. His works upon the subject were for long the standard authority. Theological conflict caused his expulsion from the Netherlands, and he found sanctuary in Paris, to which he was subsequently sent as Ambassador for Sweden. He died while on a return journey from Stockholm. Although law was his absorbing study, he was also a gifted poet, a sound historian, and a statesman of rare ability.

Grove, Sir George
b. Clapham, Aug. 13, 1820. d. Sydenham, May 28, 1900.
In early life an engineer, Grove erected the first two cast-iron lighthouses in the West Indies, and assisted in the construction of the Britannia tubular bridge. An extraordinarily versatile man, he became secretary of the Society of Arts, edited a famous magazine, edited and partly wrote the admirable Dictionary of Music and Musicians to which he gave his name, and acted as a director of the Royal Academy of Music.

Grove, Sir William Robert
b. Swansea, July 14, 1811. d. London, Aug. 1, 1896.
As distinguished for versatility as his namesake, he was famous first as a lawyer, then as a judge of the Court of Common Pleas, and, chiefly, as a great physicist. He invented the Grove voltaic battery, and greatly advanced the whole science of electricity and optics, as well by his lectures from the chair of Natural Science at the London Institution as by his books.

Guericke, Otto von
b. Magdeburg, Prussia, Nov. 20, 1602. d. Hamburg, May 11, 1686.
After a long course of study at the best Continental universities, and visiting France and England, he became engineer-in-chief in the Swedish army. Civic appointments allowed him to devote his attention to experiments, with the result that he invented the first air-pump, and fashioned the famous "Magdeburg hemispheres," which, being deprived of air, were not pulled asunder until the united strength of fifteen horses had been employed. He invented also the air-balance, and made important discoveries in electricity.

Guido d'Arezzo
b. near Paris, about 990. d. Arezzo (?), near Paris, about 1050.
It is not quite accurate to say that Guido d'Arezzo invented the notation of music, but it is indisputable that he first devised—or, at any rate, first systematically employed—the lines of the staff and the intervals between them. The importance of this advance from the chaotic conditions previously existing can hardly be overstated. He seems to have invented the F clef. Undoubtedly he gave their names to the first six notes of the scale—ut, re, mi, fa, sol, la—these being the first syllables of six lines of a hymn addressed to John the Baptist. It was Guido's boast that by his system a pupil could learn more music in five months than by previous methods he could learn in ten years. Pope John XIX. was one of his most notable and successful pupils. The reformer was a monk, and, like most other reformers, persecuted by his contemporaries.

Gurney, Sir Goldsworthy

b. Treator, Cornwall, Feb. 14, 1793. d. Reeds, Cornwall, Feb. 28, 1875.

Trevithick's experiments with the steam-engine inspired young Gurney to efforts in the same direction. The result was his steam-carriage, which, in July, 1829, ran from London to Bath and back again on the open road at the rate of fifteen miles an hour, the first vehicle driven by steam to accomplish such a journey. The success of the enterprise was immediately nullified by Parliament, which, carried away by stupidity and folly, passed laws imposing prohibitive tolls. Gurney's steam-jet, however, was very successful. It was employed by George Stephenson for his famous "Rocket," and raised its speed from twelve miles to twenty-nine miles per hour. It was successfully applied, too, to steamboats and furnaces, and had a great influence in the manufacture of iron. The so-called "Drummond light" was Gurney's invention; so was the oxyhydrogen blowpipe. In his Royal Institution lectures, where he had Faraday among his listeners, he anticipated the principle of the telegraph. He lighted and ventilated the Houses of Parliament, invented a gaslight derivable from oil, and in many ways showed himself one of the great master minds of his age. His work in connection with lighthouses was specially important.

Gustavus Adolphus

b. Stockholm, Dec. 19, 1594. d. near Leipzig, Nov. 16, 1632.

Upon succeeding to the throne of Sweden, Gustavus found upon his hands wars with Denmark, Russia, and Poland. Girt about by enemies, torn by internal dissensions, with the kingdom weakened by the loss of territory, Sweden seemed in hopeless case. Gustavus was her saviour. He had been trained to statecraft; he showed now that he was a born warrior and leader of men. He healed the feuds by which his kingdom was rent; he fired his nobles with patriotism; he encouraged commerce and learning, and gave Sweden a new spirit. Peace was concluded with Denmark; Russia was compelled to relinquish to Sweden her Baltic provinces of Livonia, Esthonia, and Courland; Poland agreed upon a six years' truce. Then came work of wider character. Austria, crushing German Protestantism, was rapidly making herself supreme, and threatening both France and Sweden. Richelieu agreed to subsidise Gustavus, and with fifteen thousand men he took the field against this gigantic foe. It was expected that this little force would be laughed off the field of battle, but it proved an army the like of which Europe had not previously known. Every man felt himself a Protestant champion. Each day was begun with prayer: it ended with prayer. The army was perfectly disciplined. It was terrible in battle, humane in victory, considerate for the people in whose country its war was waged. With readier co-operation from the people whom he had come to help, Gustavus would have swept all before him, and probably have become Emperor of Germany, saving the land from the terrible evils which threw her back a century in the march of civilisation. As it was, he was everywhere successful, but tardy support prevented his conducting operations upon a greater scale, and so permitted the atrocities of Tilly and Wallenstein. It was in battle with the latter that he fell, and his troops avenged him by winning a great victory in one of the bloodiest battles ever fought. Gustavus was one of the greatest characters in history—a scholar, an enlightened ruler, with pure and lofty purpose, and a soldier of the very highest order.

Gutenberg, Johann

b. Mainz, about 1400. d. Mainz, Feb. 2, 1468.

His father's name was Gänsfleisch, but he took his mother's maiden name, and suffered with his family when the patricians, of whom he was one, were driven by the common people from Mainz. From the cradle he seems to have shown mechanical ingenuity, and had a project in his youth for polishing stones and making mirrors. This project not succeeding, he turned his attention to printing, and was, the Germans say, the first man to invent metal type and print a book. There is some doubt as to whether the idea actually originated with him. Pictures had been printed from engraved blocks. Gutenberg's departure, however, was the first attempt at making a book independently of the pen. A man named Dritzehn and the two brothers Heilmann were his partners in the enterprise; and there was Peter Schöffer, an expert metal-worker, who made the metal types. These names occur in the controversy; while there is the legend that the first types were stolen from their inventor, Laurens Janszoon Coster, and taken to Gutenberg. After examination of all the evidence, however, German scholars credit Gutenberg with the invention. The first book produced was a Latin Bible, which appeared in August, 1455, twenty-two years before the first book printed in England made its appearance. The invention spread rapidly to other German towns, but Gutenberg did not profit. A money-lender named John Fust, who had financed him, seized his types, and he was compelled to work with inferior metals. So poor was he that he was glad to take a Court appointment, which brought him each year one suit of raiment and an allowance of food. He died in poverty and misery, though he had given to the world an art which makes it for ever grateful to his memory. Gutenberg is finely celebrated by Victor Hugo in the following passage: "A Gutenberg discovering the method for sowing the seed of civilisation and the means for the ubiquity of thought will be followed by a Christopher Columbus discovering a new field. A Christopher Columbus discovering a world will be followed by a Luther discovering a liberty. After Luther, innovator in the dogma, will come Shakespeare, innovator in art. One genius completes the other."

Guthrie, Thomas

b. Brechin, Forfarshire, July 12, 1803. d. St. Leonards, Feb. 24, 1873.

An eminent orator and philanthropist, he helped to found the Scottish Free Church, for which he raised £116,000 in eleven months, and by his writings led to the building of the first Ragged School. He was also remarkable as an advocate of temperance and compulsory education.

Guy, Thomas

b. Southwark, about 1644. d. London, Dec. 27, 1724.

The son of a London lighterman, he was apprenticed to a bookseller, set up shop himself as another, printed Bibles and Prayer-books from type imported from Holland, made much money by buying sailors' pay-tickets at a huge discount, and still more from the dealing in South Sea stock. Of this he had invested £45,000 in £100 shares, which he sold in time to avoid the crash at prices varying between £300 and £600 per share. He is commonly reputed to have been mean and avaricious, but this legend does not bear examination. During his life he established almshouses at Tamworth, and built there a town-hall. He paid the debts of innumerable people confined in the prisons of the City, and set up many deserving young men in business. He added three new wards to St. Thomas's Hospital, and built the hospital which bears his name. His will, a remarkable document, liberated six hundred persons from the debtors' prisons, and made provision for a great number of relatives and persons not related to him, provided almshouses and pensions and many other benefits. He never married, lived simply, dressed simply, and thus, it is probable, got the reputation for avarice and miserliness.

Hadley, John

b. London, April 16, 1682. d. London, Feb. 14, 1744.

By his improvement of the telescope, left imperfect by Newton and Gregory, he gave astronomers the first instrument of that kind which

was of real value to them. He also made important improvements in the invention of the reflecting quadrant, which rapidly became indispensable at sea. Hadley's younger brother George, a scientific writer (1685-1786), had his share of the family talent, and was the first man clearly to formulate the correct theory as to the trade winds. The genius of the family was not transmitted beyond this generation, for John Hadley's son, inheriting an ample fortune in money and real estate, squandered it, and died in poverty and disgrace.

Hadrian, Publius Ælius Hadrianus
b. Rome, Jan. 24, 76 A.D. d. Baiae, Italy, July 10, 138 A.D.

When forty-one years of age, Hadrian succeeded his guardian and cousin Trajan and at once inaugurated a new and beneficent policy. He realised that the era of conquest had passed, that Rome must now be wisely governed, and the Empire secured rather than indefinitely extended. Determined personally to know the needs of the Empire and its people, he undertook a journey throughout the entire dominions of Rome. Wherever he went architects and artisans accompanied him, organised like a legion, to build aqueducts, temples, fortifications, whatever he deemed necessary. The magnitude of his scheme may be estimated from the great wall bearing his name which he constructed, upon visiting Britain, from the Solway to the Tyne. Its purpose was to serve as a defence against the Picts and Scots. Seventy-three miles in length, it was in places more than twelve feet in height, and between six feet and nine and a half feet thick, and included for the accommodation of troops, stations, castles and turrets, which communicated with one another by a military way. Although no more conquests were to be attempted, his army was maintained in the highest state of efficiency. That the soldiers should not complain of the rigorous discipline which he imposed, he himself shared their hardships. He lived on the food which they had, and walked his twenty miles a day bareheaded. His laws were merciful and wise, and Rome flourished greatly under his rule. Towards the end of his life his mind seems to have weakened and to have become overcast with jealousies and littlenesses. His character was stained with bloody crimes. The one great war of his reign was waged against the Jews, of whom it was said over half a million were slain, while the Roman losses also were appalling.

Hahnemann, Samuel Christian Friedrich
b. Meissen, Saxony, April 10, 1755. d. Paris, July 2, 1843.

After studying medicine at Leipzig and Vienna, and taking his degree at Erlangen, he became convinced that old methods were wrong. The result of his investigations led to his founding the homœopathic system of medicine. The new treatment was vigorously denounced, and he was boycotted by his profession, but he courageously adhered to his work, submitted to pecuniary loss for his faith, and, moreover, made many painful experiments upon his own person for the furthering of the system which he had founded.

Haeckel, Ernst Heinrich
b. Potsdam, Germany, Feb. 16, 1834.

This distinguished German biologist was entering upon his scientific course when Darwin's "Origin of Species" made its appearance. That book determined Haeckel's career. He read it, accepted its teaching, and by his enthusiastic advocacy made the doctrine known throughout Germany. Since then Haeckel has engaged in research work of the highest value, and contributed greatly to the common stock of knowledge upon biological mysteries. Latterly he has formulated theories which Christian students of science cannot accept.

Haggard, Henry Rider
b. Bradenham Hall, Norfolk, June 22, 1856.

One of a distinguished brotherhood, he went to Natal as secretary to Sir Henry Bulwer; passed on, as secretary to Sir Theophilus Shepstone, to the Transvaal, where he hoisted the British flag at Pretoria. Afterwards returning to England, he wrote a number of successful imaginative novels. Latterly he has been engaged in investigations concerning the conditions of rural England, and has carried out important inquiries on behalf of the Government in connection with emigration schemes to the Colonies.

Hakluyt, Richard
b. Herefordshire, about 1552. d. London, Nov. 23, 1616.

The author of what has been termed "the prose epic of the modern English nation" was a Westminster scholar, and graduated at Christ Church, Oxford. His absorbing study was the history of travel and discovery, whether in Greek, Latin, Italian, Spanish, Portuguese, French, or English. He lectured on his favourite subject, and had the gratification of introducing the globes into English schools. Then he wrote an account of the discovery of America, and so gained the patronage of Lord Howard of Effingham, who took him to Paris. There he pursued with all diligence his special study, and, piqued to find Englishmen regarded as of no account in the story of discovery and adventure, he consecrated his life to writing his immortal history of the voyages, adventures, and discoveries of our national heroes. For some years before his death he was Archdeacon of Westminster, and one of the chaplains of the Savoy.

Hales, Stephen
b. Bekesbourne, Kent, Sept. 7, 1677. d. Teddington, Middlesex, Jan. 4, 1761

Although little is heard nowadays of his works, Hales was a man far in advance of his times. Upon his "Vegetable Statics" is founded our whole knowledge of vegetable physiology. He invented the artificial ventilator, and got it introduced into prisons, ships, and other buildings. He had a scheme for preserving water and meat on sea voyages, and for distilling drinkable water from the sea; and a method of registering sea depths which were by ordinary means unfathomable. Hales was a clergyman, and resided for many years in charge at Teddington. He provided a new water supply, and his entry concerning the new supply is characteristic of the minuteness with which his investigations were carried out. The outflow was such that it would fill a half gallon vessel in "three swings of a pendulum, beating seconds, which pendulum was 39 2-10th inches long from the suspending nail to the middle of the plumbet or bob."

Halifax, Charles Montagu, Earl of
b. Horton, Northants, April 16, 1661. d. London, May 19, 1715.

Statesman, poet, munificent patron of literature, friend of Newton, Addison, Congreve, Prior, and Swift, Charles Montagu is best remembered for his achievements in the House of Commons. A million of money being needed for government, he established the National Debt. A further million and a quarter being necessary, he established the Bank of England—a plan originated, by the way, three years earlier by William Patterson. He made Newton Warden of the Mint, and with his help, and that of Somers, Locke, and Halley, reformed the currency. Exchequer bills, by which the Government gets its first credit from the House of Commons, also had their origin with Montagu. His vanity and arrogance made him unpopular, and he had to take a peerage and depart to the Upper House. Two attempts to impeach him for misconduct of public affairs came to nothing. He was a grandson of the Earl of Manchester, the Parliamentary general.

Hall, Sir James
b. Dunglass, Haddingtonshire, 1761. d. Edinburgh, June 23, 1832

He was the father of three distinguished sons. John, the eldest, became a Fellow of the Royal Society; Basil, traveller and writer, made important discoveries in the Eastern seas; James was a talented artist and patron of art. Sir James's own claim to fame rests upon his having been the first geologist to embark upon experimental

geology. Hutton protested that it was impossible to judge of the great operations of the mineral kingdom from having kindled a fire and looked into the bottom of a little crucible. But time justified the chemical tests of the baronet, and it was in his laboratory that experimental geology, from which we have learned so much, had its birth. He was the inventor of an instrument for registering high temperatures.

Hallam, Henry
b. Windsor, July 9, 1777. d. Penshurst, Kent, Jan. 21, 1859.

The son of a Canon of Windsor and Dean of Bristol, he took his degree at Oxford, and then held the post of Commissioner of Stamps. Upon inheriting his father's fortune, he devoted himself to literature, and by his "Europe During the Middle Ages," his "Constitutional History," and his "Introduction to the Literature of Europe," placed himself in the very front rank of historians. He is severe, but accurate; austere, but learned and judicious. Arthur Henry Hallam, of Tennyson's "In Memoriam," was one of his eleven children, of whom only four survived to cheer his old age.

Haller, Albrecht von
b. Bern, Switzerland, Oct. 16, 1708. d. Bern, Dec. 12, 1777.

Here the boy was truly father of the man. Before he was ten he had drawn up a Chaldee grammar and a Greek and Hebrew vocabulary, and compiled a great collection of biographies. He risked his life to rescue from fire his translations of the classics, and afterwards burned them. After a course of study at the best universities, he rapidly qualified to rank as one of the greatest anatomists and physiologists of his century. He filled the chair of medicine, anatomy, botany, and surgery in the new University of Gottingen, and attained a European reputation by his industry, his original researches, and his success as the leader of a new school of learning.

Halley, Edmund
b. Haggerston, London, Nov. 8, 1656 d. Greenwich, Jan. 14, 1742.

The great astronomer was the son of a rich soap-boiler, who gave him an excellent education, and when sending him to Oxford presented him with a large telescope. Before he had reached manhood, Halley devised a new method of determining the elements of the planetary orbits; he then resolved to catalogue the stars in the Southern Hemisphere by way of complementing the efforts of Flamsteed and Hevelius in the Northern Hemisphere. During his stay at St. Helena, he observed a transit of Mercury across the sun's disc, and by so doing arrived at his method of ascertaining the solar distance. His successful charting of 360 stars and his other important discoveries led to his being termed the "Southern Tycho." Honours and more notable labours followed, and then his inquiries into gravity brought him into association with Newton, whose "Principia" he published at his own cost when, at Halley's earnest solicitation, Newton had written it. Halley's other work, undertaken with a view to solving problems as to the variation of the compass, the discovery of Southern lands, and his observations enabling him to predict the return of the comet named after him, was all-important and valuable as opening new horizons for the men who were to follow after.

Hamilcar, Barca
b. Carthage, North Africa, about 260 B.C. d. Spain, 228 B.C.

"Barca," his surname, is the Jewish term for "lightning," and refers to the character of the military operations of this great warrior and statesman. In his day, Carthage was the great rival of Rome, and had colonies in Sicily, Corsica, and Sardinia. Hamilcar died in the attempt to add Spain to the Carthaginian possessions and to make it a centre for an attack upon Rome. In the first Punic war he landed in Sicily with a small army, at first little better than savages, but afterwards moulded by his will into a magnificent fighting force. He maintained himself for three years on Mounte Erete against the Romans, who for the whole time were in possession of the rest of the island, save for two additional strongholds which he held but they blockaded. To raise the blockade, he moved to what is now Mount St. Giuliano, and there for two years withstood the onslaughts of the Romans. At length overwhelming numbers defeated him, and brought to an end the first Punic war. Returning with his army to Africa, he was unable to obtain the pay for his soldiers, and was called upon to subdue a formidable insurrection. This accomplished, he became commander of all the Carthaginian forces, and, having sworn his eldest son, Hannibal, to eternal hatred and enmity to Rome, he set out with a picked force for Spain. Some parts of the country he subdued by force of arms; other parts he won to allegiance by statesmanship. He died, however, before he could complete his plans, slain in a battle between the Tagus and the Douro. His son Hannibal carried on his task.

Hamilton, Sir William Rowan
b. Dublin, Aug. 4, 1805. d. Dunsink, near Dublin, Sept. 2, 1865.

He was a phenomenal boy, could speak thirteen languages by the time he was twelve, had mastered all the ordinary University course at fifteen, and entered upon original research. He distinguished himself in astronomy, acting as Irish Astronomer Royal, but is specially celebrated as the inventor of quaternions, a calculus of peculiar power and generality.

Hampden, John
b. London, 1594 d. Thame, Oxfordshire, June 24, 1643.

A cousin of Oliver Cromwell, and a member of a distinguished old Buckinghamshire family, Hampden came into prominence in Parliament by his resistance of the loan which Charles I. attempted unconstitutionally to raise. He was conspicuous in the impeachment of Buckingham and Strafford. It was his resistance of the Royal demand for ship-money, however, which made him a national figure. He undertook the expense of fighting the case, and though seven of the twelve judges decided against him, the patriot had the sympathy and approval of all right-thinking men in the country. Hampden was one of the five members whom Charles I. sought to arrest in the House of Commons. That act brought on the Civil War. Here Hampden, who subscribed £2,000, and took an active part in the campaign of the Parliamentarians, showed courage and ability. He died from the effects of a bullet-wound sustained while attempting to counter a foray of Prince Rupert from Oxford. Hampden was a great patriot, and a noble Christian gentleman.

Handel, George Frederick
b. Halle, Germany, Feb. 23, 1685. d. London, April 14, 1759

The son of a Halle surgeon, he was regarded, almost from infancy, as a musical prodigy, and was given the best musical education his father could afford. Before he was twenty he had written and produced his first opera. He played in a Hamburg orchestra, gave lessons, wrote minor pieces, and then made a triumphal progress through Italy. Returning to Hanover, he was made Chapelmaster to the Elector, our own George I. It was in 1710, when he was five-and-twenty, that he came to England, which from that time became his home. Ten years later the Royal Academy was founded, "to secure a constant supply of operas by Handel." That scheme did not long flourish. Handel wrote opera after opera, but quarrels with rivals and with his singers brought him eventually to bankruptcy, and for the time being unhinged his mind. It was upon his recovery that he began what was to be the work of his life—his oratorios. Fifteen of them he produced in a dozen years. His sight, long failing, now deserted him, but he still continued to compose and to give his magnificent organ recitals. Altogether, he wrote a score of oratorios, twice as many operas, hundreds of cantatas, psalms, songs,

and instrumental pieces. His industry was inexhaustible, his fertility so phenomenal that some of his greatest works are said almost to have been improvised. He treated all styles, and he excelled in all. No man ever more richly dowered the world with sublime, inspiring melody.

Hannibal
b. Carthage, North Africa, 247 B.C. d. Bithynia, Asia Minor, about 183 B.C.

When nine years of age, Hannibal, eldest of the "lion brood" of Hamilcar, the great general, was compelled by his father to swear on the altar of sacrifice a vow of eternal enmity to Rome. He was then permitted to accompany his father from Carthage to Spain. At the death of Hamilcar, the command evolved upon his brother-in-law, but Hannibal became supreme, and proceeded to give effect to that part of Hamilcar's plan which death had caused to be left unfinished. He completed the conquest of Spain, all save one stronghold – Saguntum, which was in friendly relations with Rome. By attacking and reducing this he made all Spain a Carthaginian province, and brought on the second Punic war. With an army which finally dwindled down to 40,000 infantry, 6,000 cavalry, and fewer than two score elephants, he crossed first the Pyrenees and then the Alps, a daring, grandiose scheme, which only the greatest soldier of all time could have carried through. It was a war for the conquest of the world in which he was now engaged a world ruled by Carthage or Rome. In battle after battle he inflicted appalling losses upon the Roman armies ... never knew defeat in all the sixteen years in which he overran Italy. Reinforcements which were being sent to him from Spain were cut off. He was recalled to defend Carthage from a Roman invasion, and at last Scipio won a decisive triumph over him. Hannibal's veterans, outnumbered, were cut to pieces; his raw levies fled. Carthage was already conquered before Hannibal appeared upon the scene; his small army could not avert the ruin. He now turned his genius to statesmanship, but his enemies caused him to flee, first to Antiochus of Syria, next to Bithynia, where, still pursued by the vindictive Romans, he took poison. Hannibal has been called at once the Burke, the Pitt, and the Wellington of his country. He was a great statesman, and the finest general in history. He only just failed to make Carthage mistress of the whole world.

Hansom, Joseph Aloysius
b. York, Oct. 26, 1803. d. London, June 29, 1882.

The inventor of the cab, which still retains his name, was apprenticed to his father, a carpenter, but showed great skill as a draughtsman. He attended a night school, improved his scanty education, and became a famous architect. His churches, mostly Roman Catholic, are to be seen in many parts of England, and even in Australia and South America. His church at Preston St. Walburge's has a spire 306ft. high, the loftiest built in England since the Reformation.

Hanway, Jonas
b. Portsmouth, Aug. 12, 1712. d. London, Sept. 5, 1786.

Left fatherless at an early age, he was apprenticed to a Lisbon merchant, and became a great traveller for commercial purposes. Inheriting a small competence, he devoted the remainder of his life to social and philanthropic work to such schemes as the paving of London, the care of foundling children, of sweeps' boys, and outcast women, prison reform, and the establishment of Sunday-schools. He was the first Englishman to carry an umbrella, and after thirty years of derision saw his invention generally popular.

Hardy, Thomas
b. near Manchester, Dorsetshire, June 2, 1840.

The novelist and poet of Wessex scenes and life began his career as an architect. "Far From the Madding Crowd" and later novels—notably, "The Return of the Native" and "Tess of the D'Urbervilles"—have given him a unique place among English artists in fiction. He writes with great imaginative power, tinged with pessimism. Latterly he has forsaken fiction for historical drama.

Hare, Robert
b. Philadelphia, Jan. 17, 1781. d. Philadelphia, May 15, 1858.

He was a famous chemist of his day, and added notably to the science in which he was interested. His material gift to the world was the calorimeter, an instrument for measuring the specific heat of a body. He invented also an oxyhydrogen blowpipe, but in that he had been anticipated by the English inventor, Sir Goldsworthy Gurney.

Hargraves, Edmund Hammond
b. Gosport, Hants, Oct. 7, 1816. d. Sydney, N.S.W., Oct. 29, 1891.

The man who was destined to discover the Australian goldfields went to Australia in 1832, and after narrowly escaping death settled down to sheep-farming for fifteen years. He joined in the rush to the Californian goldfields. Arrived there, his knowledge of geology told him that the geological formation was similar to that of the quartz rocks of the Blue Mountains, New South Wales. He returned to Australia, put his theory to the test, and at once found gold. His discovery was unselfishly communicated to the Government, and a new era for the island continent opened.

Hargreaves, James
b. Blackburn (?), about 1720. d. Nottingham, April, 1778.

The inventor of the spinning jenny was an illiterate weaver, who began life as a carpenter. His mechanical skill being detected by the grandfather of Sir Robert Peel, he was set to work to improve the carding machine. An accident the overturning of one of the old hand spinning-wheels – revealed to Hargreaves possibilities of a different system of construction, and he secretly made the spinning jenny, which would spin wool, cotton, or flax into a plurality of threads at the same time and by one operation. It was the first advance of the sort from the old plan of manual labour. When the invention became known, jealous workmen smashed the machine and demolished Hargreaves' house. Like Arkwright, he was driven to Nottingham. Here he entered into partnership with a man named James, and patented his machine. He seems to have made little out of it, Lancashire manufacturers pirating the invention, and leaving his family to poverty when he died.

Haroun-Al-Raschid
b. near Teheran, March 20, 763 (?), A.D. d. near Khorassan, Persia, 809 A.D.

The hero of so many stories in the "Arabian Nights" was the most famous of all Arabian califs, the most learned man of the then most learned people in the world. His dominions extended from Egypt to the Indus; his Court was the home of the most brilliant company of scholars, poets, grammarians, cadis, and scribes ever assembled round one calif. Ascending the throne when twenty-two years of age, he entrusted the Government to the famous Barmecide family, and saw to it that frontiers were strengthened, commerce developed, and learning encouraged. Five years before his own death, however, in an insane fit of jealousy, he had the Barmecides put to death. This was the one blot upon an otherwise noble character. As a warrior he overran Asia Minor at the head of a splendid army, and died while suppressing an insurrection at Khorassan. He several times made the pilgrimage to Mecca, and, despite the murder of the Barmecides, was renowned for humanity and chivalry. At the coronation of Charlemagne he sent, among other gifts, the keys of the Holy Sepulchre. Mediæval culture owed much to the intellectual splendours of the reign of "Aaron the Just," as he was called.

Harriot, Thomas
b. Oxford, 1560. d. Isleworth, Middlesex, July 2, 1621.

Having graduated at Oxford, he became mathematical tutor to Sir Walter Raleigh, through whose influence he was sent as surveyor with Sir Richard Grenville's expedition to Virginia. The result of his labours was the presentation of one

of the earliest examples of a statistical survey on a large scale. Harriot was one of the famous scientists who bore Henry Earl of Northumberland company during his imprisonment in the Tower. With Walter Warner and Thomas Hughes he used to go there daily, and dream and solve problems. He was warned that if he did not make his discoveries public he would be anticipated, and he was: Viète, the French mathematician, anticipated his publication of the discovery upon which modern algebra is based. Still, Harriot carried the subject further than his contemporary, and it is claimed for him that but for his foundation Descartes' whole superstructure would have been impossible. The Earl of Northumberland gave him a pension and quarters at Sion House, and there he died.

Harrison, Frederic
b. London, Oct. 18, 1831.

After a distinguished career at King's College School, London, and at Oxford, he was called to the Bar, and practised conveyancing and equity. It has been as a publicist and man of letters, however, that he has taken a foremost place. He has striven unceasingly for popular rights, and as the intellectual leader in England of the Positivists has laboured without remission to win converts to the doctrines of Auguste Comte. He has been Professor of Jurisprudence and International Law at Lincoln's Inn Hall, and served upon Royal Commissions.

Harrison, John
b. Foulby, Yorks, March 24, 1693. d. London, March 24, 1776.

The inventor of the chronometer was the son of a carpenter who knew a little about clock-making, and set his boy to walk in like paths. But the boy was a genius, though he had to dispense with the education of one. He made a clock all of wood, then one with his famous "gridiron" pendulum, which was so constructed that changes of temperature did not affect the timekeeping. At this time navigation was very much a haphazard matter, so the Government offered three prizes—£10,000, £15,000, and £20,000—for the discovery of a method of determining the longitude at sea within sixty, forty, and thirty geographical degrees respectively. Harrison, with nothing but native genius to help him—no education and no models to suggest a plan—devoted the best years of his life to the task. He made four timepieces, each better than its predecessor, until, after voyages to and from Jamaica, and to and from Barbados, it was found that he had determined the longitude within ten miles, or twenty miles better than the distance required to qualify him for the first prize. He was submitted to scandalous indignities, his money withheld, and petty sums offered by way of solatium. He was friendless, but he had earned the prize, and he persisted with petition after petition until eventually, little by little, he got the sum due to him. But it cost nearly a lifetime to obtain the money. The prize was offered in 1713; he won it in 1762; he got his money in 1773, when he was within less than three years of the grave.

Harvard, John
b. London, 1607. d. Charlestown, Mass., Sept. 14, 1638

The principal founder of the famous Harvard University was the son of a Southwark butcher. His mother was thrice married, and, deriving property from each husband, left John the Queen's Head public-house, Southwark. He graduated at Cambridge University, married, and went to America, where he officiated as minister at Charlestown. In his will he left £700 and a library of 320 books to the college then about to be built. It was called Harvard in his honour.

Harvey, William
b. Folkestone, Kent, April 1, 1578. d. London, June 3, 1657.

The discoverer of the circulation of the blood came of good old Kentish yeoman stock, and was given the advantage of a first-class education, not only in England, but in Italy, where the schools of medicine were already famous, and where he was privileged to hear Galileo and Fabricius of Aquapendente. The latter had already made known his discovery of valves in the veins, tending to a flow of the blood in a special direction. Many minds were concentrating on the problem as to the blood, and controversy afterwards raged as to whether or not Harvey really discovered the truth. He did. Other inquirers had got some glimmering of the truth, but they had inverted the facts. To Harvey alone is due the credit for demonstrating that the perpetual motion of the blood in a circle is produced by the beat of the heart. The grand discovery was announced quite informally in discourses before the College of Physicians in their lecture-hall at Knightrider Street, near St. Paul's, and the MSS. of the lectures are still preserved at the British Museum. For some years after his return from the continent, Harvey acted as physician to St. Bartholomew's Hospital, where he had a salary of £33 6s. 8d. per year and no residence. He was in favour at Court, being successively physician to James I. and Charles I. He accompanied the latter as medical attendant during the Civil War until the surrender at Oxford.

Haussman, George Eugène
b. Paris, March 27, 1809. d. Paris, Jan. 11, 1891.

To all who love Paris, with its noble boulevards, its open spaces, its many fine bridges, and its beautiful parks, Haussman is indeed a great man. It was he whom Napoleon III. entrusted with the making of the modern Paris, when, having thrown up the Bar, he entered the Civil Service. He carried out the whole work for water supply and sanitation, in addition to the embellishment of the entire capital. The work left Paris with a debt of thirty-five million pounds, and caused his dismissal. Turning bank director, and then being elected a deputy, he was still dogged by evil fortune, and died in poverty.

Hauy, René Just Abbé
b. St. Just, France, Feb. 28, 1743. d. Paris, June 3, 1822.

His parents were so poor that it was only through the charity of friends that he was educated. He underwent his course at college amid almost incredible privations and misery. The accidental fall of a treasured specimen of calcareous spar led him, on examining the fragments, to discover the geometrical law of crystallisation. He devoted his life to mineralogy with important results. He was given an honorary canonry at Notre Dame, hence he is generally spoken of as the Abbé Haüy. His brother Valentin—like himself, poor all his days—consecrated his life to the education of the blind poor.

Havelock, Sir Henry
b. near Sunderland, April 5, 1795. d. Lucknow, India, Nov. 24, 1857.

This great Christian soldier was the son of a wealthy shipbuilder, and was to have been a lawyer, but, like his three brothers, entered the Army. He went to India, where he was converted and publicly baptised. He had an active part in all the fighting of his time, and his crowning work was, during the Mutiny, to relieve Lucknow. There he died two months later, killed by work and worry and responsibility. When the tidings of his great feat reached England, Parliament voted him a baronetcy and a pension of £1,000 a year. But they were voting the reward to a man who, though they did not know it, was already in his grave.

Hawke, Edward, Lord
b. London, 1705. d. Sunbury, Middlesex, Oct. 17, 1781.

The son of a barrister, he took early to sea, and when thirty-nine was dismissed the Service for a too great success. He was in command of the Wolf, and broke from the line of battle at Toulon to engage and defeat a French ship. For this breach of discipline he was dismissed, but was restored as an act of Royal favour, and lived to defeat the French fleet which, under Admiral

De Conflans, was to have covered an invasion of England. He was raised to the peerage, and given a pension of £2,000 per annum.

Hawthorne, Nathaniel
b. Salem, Mass., July 4, 1804. d. Plymouth, U.S.A., May 19, 1864.

A dreaming, solitude-loving boy, Hawthorne, son of a merchant captain, was left much to his own resources from an early age, his father dying when he was four. The love of isolation never left him. He lived, as a boy of fourteen, at a lonely farm in the woods of Maine, and as a man he became one of the Brook Farm community, where, with one or two other men, he tried the experiment of running a farm on idyllic semi-socialistic lines. He shut himself up for a dozen years in complete seclusion before he gave the world his first novel—"Fanshawe." America would have none of his works, but his writing found immediate acceptance in England, where to the end his reputation was higher than in his own land. England, indeed, set the Hawthorne vogue. For many years his circumstances were not easy, and he had to take employment as weigher and gauger in a customs house, while afterwards he held a consular appointment for four years at Liverpool. His income grew in time, and he was able to travel Europe, and finally to end his days rich in this world's goods—and rich, too, in honour. His writings are simple but melodious, full of fine feeling and insight. His reputation is still increasing and will increase.

Hay, John
b. Salem, Ind., U.S.A., Oct. 8, 1838. d. July, 1905.

Having been called to the Bar, he became assistant private secretary to President Lincoln, of whom, in conjunction with another writer, he produced an excellent biography. Famous as a statesman of wisdom and high ideals, he is best loved as the author of the delightful poems "Pike County Ballads," of which "Breeches" suffices to ensure his immortality.

Haydn, Joseph
b. Rohrau, Austria, March 31, 1732. d. Vienna, May 31, 1809.

He was wretchedly poor, only a wheelwright's son, and when his term as a soprano in the choir of a Vienna church ended he had a hard fight for bare existence. But genius burned, and a man of discrimination hearing a composition of Haydn's played by the composer himself in the street, commissioned him to write an opera. Haydn seized his chance. His opera was a success. It brought him introductions to influential people, and finally got him a lucrative appointment. He had to come to England, however, before he was truly appreciated. Here, in two visits, he produced his twelve great symphonies. Thereafter he composed his magnificent oratorios. The importance of Haydn to the world has been thus impressively expressed by the Right Hon. A. J. Balfour: "Without Haydn we should not have the Mozart we know; without Mozart we should not have the Beethoven we know; and without Beethoven the whole musical history of the nineteenth century would have been utterly different from what it is."

Hazlitt, William
b. Maidstone, Kent, April 10, 1778. d. London, Sept. 18, 1830.

"Well, I've had a happy life," he said with his last breath. The statement does not quite accord with fact. He was twice unhappily married, and had a stupid love affair with a woman intellectually his inferior. But there was something lovable in the man who could command the friendship of Lamb, Leigh Hunt, and Coleridge. He quarrelled, where it was possible, with all his friends, but Lamb was loyal and true to the last. Hazlitt tried his hand at painting without success. His contributions to literature are unequal. At his best he is very fine, and his reputation has been greatly enhanced of recent years. He was a master of epigram and of virile, nervous English. His father was a Unitarian minister, and Hazlitt himself studied for the Church. His early meeting with Coleridge dissuaded him from his original intention, and turned his thoughts first to art and then to literature.

Heathcote, John
b. Duffield, near Derby, Aug 7, 1783. d. Tiverton, Devon, Jan. 18, 1861.

He was the son of a Leicestershire farmer, and was apprenticed first to a hosiery manufacturer, then to a stocking-maker and framesmith. His indentures completed, he worked as a machine-builder, and bought out the man by whom he had been employed at Nottingham. Then he turned his attention to the construction of a machine which would do for lace what the loom had done for stockings by superseding the knitting-needle. For his purpose he took himself to Hathern, a little town near Loughborough, and carefully worked out his scheme—first on paper, then expressed in material form. The outcome was that at twenty-four years of age he had perfected what was described as the most complicated machine ever produced. The first square yard of net made by the machine sold for five sovereigns, 240 times the price which it would now command. Here, then, was the origin of the enormous lace industry which has meant so many millions sterling to Midland England. Heathcote was not long permitted the quiet enjoyment of his reward. The Luddites demolished the machines which he had erected in his Nottingham factory, and he was awarded £10,000 by the country, but never got the money. He moved to Tiverton, set up new machinery, constantly added improvements, invented a steam plough, sat in Parliament, built schools, and died wealthy and honoured.

Heathfield, George Augustus Eliot, Lord
b. Stobs, Roxburghshire, Dec. 25, 1717. d. Aix-la-Chapelle, July 6, 1790

The gallant defender of Gibraltar was educated at Leyden University and the French military school of La Fère, as well as at Woolwich. He saw a great deal of fighting on the Continent before being sent to Gibraltar. He had some time in which to strengthen the defences of the fortress, but his defence for three years was one of the greatest achievements in the annals of war. Not only had he to withstand the combined assaults of fleet and army; the fortress was blockaded by sea and land, and the garrison was all but starved. While solicitous for the comfort of his men, he was himself of the simplest habits—a vegetarian, and total abstainer from alcohol. His peerage was granted in recognition of his valorous defence.

Heber, Reginald
b. Malpas, Cheshire, April 21, 1783. d. Trichinopoly, India, April 3, 1826.

After a distinguished career at Oxford, where his prize poem "Palestine" attained lasting fame, he accepted a country rectory in Shropshire, but was called to India as Bishop of Calcutta, and there died. His literary reputation rests upon his collection of hymns, of which "From Greenland's Icy Mountains," "The Son of God Goes Forth to War," and "Holy, Holy, Holy," are sung in every Christian land.

Hedley, William
b. Newburn, Newcastle, July 13, 1779. d. Lanchester, Durham, Jan. 9, 1843.

One of the pioneers of the age of steam, he has received less credit than he deserves. Working in a colliery, he perceived the need for better methods of hauling the coal from the pit-mouth to the Tyne, and, scorning the old toothed rails and cogged wheels with which locomotives were first invented, he devised and patented the smooth rail which we still use. He was among the first to use the steam blast for furnaces, and to apply steam for the purposes of barge propulsion.

Hegel, George Wilhelm Friedrich
b. Stuttgart, Germany, Aug. 27, 1770. d. Berlin, Nov. 14, 1831.

Destined by his parents for the Church, Hegel preferred the career first of tutor, and afterwards of professor. In the latter capacity he drew crowds of students to Heidelberg, and, later, to Berlin, and became the philosophical dictator of Germany. He established two different schools of thought. One of these interpreted his philosophy as true Christian theism; the other, as a pantheistic and

eventually materialistic direction, denying both the personality of God and the immortality of the soul.

Heine, Heinrich
b. Dusseldorf, Prussia, Dec. 13, 1799. d. Paris, Feb. 17, 1856.

Poetry was to Heine a "holy plaything." His writings on religion, philosophy, and politics were often merely vehicles for his wit and cynicism. Yet their revolutionary character made his native Germany no place for him, and he spent the last twenty-five years of his life in Paris, drawn thither by the Revolution of 1831. By that time he had established his fame upon a firm foundation with his "Buch der Lieder" and "Reisebilder." These caused him to be hailed as the successor of Goethe. But born a Jew, and compelled to become a member of the Lutheran Church in order that he might practise law in accordance with the terms upon which he drew an allowance from a wealthy uncle, he became very unpopular with his compatriots. His best work was done before he was thirty. When he was in his fiftieth year he was laid low by spinal paralysis. He suffered tortures, and was confined to his bed for the remainder of his life. In that period, however, mastering pain and infirmity, he wrote much which will assist in maintaining his reputation as one of the greatest of modern poets.

Helena, St.
b. third century A.D. died about 328.

Supposed to have been the daughter of an innkeeper, she became the wife of Constantius Chlorus, who, upon being made emperor, was compelled to divorce Helena and take a wife of more exalted birth. Her only son was Constantine the Great. When he became Emperor of Rome, and a convert to Christianity, she, too, was converted, and, proceeding to Jerusalem, discovered the Holy Sepulchre and the Cross.

Heliodorus
b. Emesa, Syria, fourth century A.D. d. close of fourth century, A.D.

The earliest and best of the Greek romance writers was a member of a family of pagan priests, but himself became a Christian, and was Bishop of Tricca, in Thessaly. He is famous as the author of "Æthiopica," which became the model for all later Greek romance, and has inspired many modern writers. It has been translated into every written language.

Helmholtz, Hermann Ludwig Ferdinand von
b. Potsdam, Germany, Aug. 31, 1821. d. near Berlin, Sept 8, 1894.

One of the world's greatest mathematicians and physicists, he was so poor early in life that he had to begin his career as an army surgeon. His discoveries in physiology soon attracted attention, and brought him a professorship at Königsberg, followed by still higher appointments at Bonn, Heidelberg, and Charlottenburg. His investigations covered an immense field, and to whatever subject he turned it was to bring to light new data. He revolutionised the science of the ear; he opened a new world to the eye specialists; he threw new light upon the nervous system. In chemistry, mathematics, electricity, magnetism, meteorology and theoretical mechanics he was no less successful.

Helmont, Johann Baptist van
b Brussels, 1577. d. near Brussels, Dec 30, 1644.

After several years' devotion to mysticism he turned his attention to chemistry, and helped to reduce it to order out of the chaos to which it had been brought by the alchemists. He was the first to use the balance in chemistry, and gave science the word "gas." His discoveries marked a new departure for a future generation of scientists.

Hemans, Felicia Dorothea
b. Liverpool, Sept. 25, 1793. d. Dublin, May 16, 1835.

For many years this gifted woman was an invalid, and some of her most charming poems were produced during intervals of intense suffering. Her genius was not of the highest order, but lyrics like "The Treasures of the Deep," "The Better Land," "The Homes of England," "Casabianca," "The Palm Tree," "The Graves of a Household," and "The Wreck," may last as long as the language in which they are written. She was the daughter of a Liverpool merchant named Browne, whose reverse of fortune caused his removal to Wales, where she grew up in an atmosphere of romance and mysticism. She married in 1812 an Irish officer. They had five sons; then her husband left her, and they never afterwards met.

Henderson, Alexander
b. Creich, Fifeshire, about 1583. d. Edinburgh, Aug. 19, 1646.

The son of a Fifeshire tenant farmer, he was appointed by Archbishop Gladstanes to the living of Leuchars. The appointment was so unpopular, proceeding from a prelate, that Henderson, for his induction service, had to enter the church by way of a window. He soon identified himself with the popular cause, attained to fame, disputed with Charles I. on public and ecclesiastical affairs, and drafted the National Covenant and the famous Solemn League and Covenant. He was foremost in restoring to the Kirk of Scotland her ancient rights and liberties.

Henry IV. of France
b. Pau, France, Dec. 13, 1553. d. Paris, May 14, 1610.

The author of the Edict of Nantes, which gave perfect religious equality to France, was bred a Huguenot, and as one made himself famous at the head of the Huguenot army. He escaped the massacre of the Huguenots by submitting to Rome, but when at liberty repudiated his conversion, only to recant once more, saying, "Paris is well worth a Mass." By great skill as a general and diplomatist, he overcame all his enemies, and became King of France. He was a wise and humane ruler. To him France owes the inception of her industries; to his gifted Minister Sully the reorganisation of her finances. He planned a great scheme for the union of all the countries of Europe into a federal republic, but was assassinated by a Jesuit fanatic before the world could become acquainted with the details of his plan.

Henry I. of Germany
b. Saxony, 876. d. Saxony, July 2, 936.

Surnamed the Fowler, because of his love of the chase, Henry I. was the promoter of the unity and civilisation of Germany. He expelled the Hungarians, made Austria part of the German Empire, recovered Lorraine, gave the country fortified cities in place of squalid villages, and, great as a statesman and warrior, played a notable part in the upraising of his own country and of Europe generally. Henry II. "St. Henry"—another great soldier and administrator and a zealous Christian monarch, was the great-grandson of the Fowler.

Henry II. of England
b. Le Mans, France, March 5, 1133. d. Chinon, France, July 6, 1189.

Expediency rather than principle dominated the life and actions of this first Plantagenet king. His reign was important to posterity, because of his great legal reforms. He substituted the jury for trial by battle, established assizes and the High Court of Justice. One of the great blots upon his reign was the murder of Becket. From his eldest daughter—Maud—by her marriage to Henry V., Duke of Saxony, the present royal family of Great Britain is descended.

Henry VIII. of England
b. Greenwich, June 28, 1491. d. Westminster, Jan. 28, 1547

Of this King, son of Henry VII. and Elizabeth of York, it has been said that he approached as nearly as possible to the ideal standard of perfect wickedness as the infirmities of human nature would allow. Yet it is impossible to exclude him from the roll of men who have achieved great results. Not because he was more Protestant than his predecessors, but from quite other motives, he overthrew the supremacy of the Pope in England, made the sovereign of this land head and "defender" of the Church, and suppressed

monasticism. He had six wives. The first and fourth he divorced; the second and fifth he beheaded; the third died, after giving birth to the future Edward VI.; the sixth was so fortunate as to survive him.

Hero
b. Alexandria.

The fame of Hero—or Heron—survives, but the exact dates of his birth and death—about 3rd century B.C.—it is impossible now to ascertain. He was a pupil of Ctesibius, the father of hydromechanics, and first applied science to industry. He knew the use of steam, and invented what was practically a primitive steam-turbine. He anticipated by two thousand years the modern hot-air engines, devised an instrument for surveying which was the forerunner of the theodolite, and left valuable writings on pneumatics and on other scientific subjects. His discoveries served no useful purpose in his own age, but they demonstrate wonderfully the genius and skill of the man and of the great Alexandrian school to which he belonged.

Herodotus
b. Halicarnassus, Asia Minor, 484 B.C. d. Thurii, Italy, 424 B.C.

Although a Greek, the great historian of antiquity was born a Persian subject, and helped, it is believed, in the overthrow of the Persian power and in making his native town part of the Athenian union. He travelled throughout Greece, familiarised himself with every part of the coast of Asia Minor, and with Egypt, and lived in Samos and Athens. Considerable as were his travels, he found time for extensive study, and was familiar with the whole range of Greek literature extant in his age. Wherever he travelled, he made himself master of all that there was to be learned of history and institutions, manners and customs. So he equipped himself for his great work, the writing of his History, whose charm to-day is as potent as ever, and whose authenticity is more and more firmly established by modern research. Herodotus was not only the father of history; he was, as De Quincey has called him, the general father of prose composition.

Herschel, Sir William
b. Hanover, Nov. 15, 1738. d. Slough, Bucks, Aug. 25, 1822.

The son of a bandmaster, and himself a professional musician in his youth, he educated himself in mathematics and astronomy, and, too poor to buy a reflecting telescope, made one for himself. Famous among his discoveries was that of the planet Uranus. Herschel was the virtual founder of sidereal science. He was notably assisted in his labours by his brilliant sister Caroline Herschel—who made important astronomical discoveries of her own.

Herschel, Sir John Frederick William
b. Slough, Bucks, March 7, 1792. d. Collingwood, Kent, May 11, 1871.

Herschel's father had but one rival as an explorer of the heavens, and that rival was his greater son. The latter carried on the work which his father had begun, and enormously increased our store of astronomical data. After re-examining his father's work, he published a catalogue of a vast number of stars and nebulæ, and, having exhausted the Northern Hemisphere, completed his work by exploring and cataloguing the stars of the southern one. He was a distinguished chemist, to whom photography owes much; while as a man of letters he made notable contributions to English literature, in the form of translations from the Greek and German.

Hertz, Heinrich Rudolf
b. Hamburg, Feb. 22, 1857. d. Bonn, Germany, Jan. 1, 1894.

One of the most brilliantly successful of modern physicists, Hertz began his career as an engineer, but happily abandoned that vocation for the pursuit of physical science. Following up the work of Faraday and Clerk-Maxwell, he added greatly to the advancement of knowledge of electricity—in its relation to light. His most important discovery is commemorated by the name given to the Hertzian waves.

Hesiod
b. Beotia, Greece, about ninth century B.C. d. Orchomenus.

The father of Greek didactic poetry exercised so great an influence over the minds of his countrymen that he is said, with Homer, to have created the religion of the ancient Greeks. He wrote not to please, but to instruct. Scholars are not agreed as to how many of the works attributed to him were really his, how many received his name which really belonged to the school of poetry which he founded. His career is enshrouded in obscurity, and dates cannot be given with any certainty.

Hill, Matthew Davenport
b. Birmingham, Aug. 6, 1792. d. near Bristol, June 7, 1872

Eldest brother of Sir Rowland Hill, he was as conspicuous for efforts on behalf of the reform of the criminal law as Sir Rowland was in connection with postal reform. He was successively Member of Parliament, Recorder for Birmingham, and Commissioner of Bankrupts, but his greatest efforts lay in the direction mentioned. He was one of the pioneers of the movement for reformatories for juvenile criminals, a work attended by great benefit to the community.

Hill, Sir Rowland
b. Kidderminster, Dec. 3, 1795. d. Hampstead Aug. 27, 1879.

When Hill was a young man it cost 1/4½ to send a letter from London to Edinburgh, and absorbed a fifth of the wages of an Irishman labouring in England who wished to send home a letter. Hill repeatedly witnessed the fear of his mother that a letter should be delivered at her house for which she should be unable to pay. He saw that illicit methods were employed to get letters conveyed, and that the public revenue from the Post Office, instead of increasing with the growth of the national wealth, steadily decreased. His scheme of penny postage was the result of his own personal experiences. It was strongly opposed by the postal authorities, who predicted terrible consequences from its adoption; but by patience, skill, and courage he carried his scheme in the face of almost unprecedented opposition. Appointed finally Secretary of the Post Office, he saw the number of letters dealt with by the Post Office increased from 76 millions to 642 millions a year, and the revenue raised from 2¼ millions sterling to upwards of 3¾ millions. Few men of the nineteenth century accomplished a more notable work for the nation.

Hipparchus
b. Nicæa, Asia Minor, second century B.C. d. Nicæa, about 120 B.C.

The founder of scientific astronomy conducted his experiments with instruments falling short a hundredfold of the precision of those now in use, but his discoveries were of great importance. He catalogued a great number of stars, discovered the eccentricity of the solar orbit, some of the inequalities of the moon's motion, the precession of the equinoxes, and did much in the application of astronomy to geography. Hipparchus was a man of towering intellect, who, armed with the crudest implements, achieved results which, for centuries afterwards, were the basis of all scientific knowledge in the paths he had chosen.

Hippocrates
b. Island of Cos, about 460 B.C. d. Larissa, Greece, about 377 B.C.

The greatest physician of ancient times, a profound scholar and philosopher, Hippocrates was not only the founder of the art of medicine, but prepared the way for men like Aristotle and the great school of Alexandria. Nearly fourscore works bearing his name are in existence. Many of these are forgeries or wrongly attributed to him. A sufficient number of writings incontestably his remains for us to reconstruct the splendid learning of which he was the founder.

Hobbes, Thomas
b. Westport, Wilts, April 5, 1588. d. Hardwick Hall, Dec. 4, 1679.

Scholar and philosopher, associate of Bacon, Galileo, and other intellectual giants, Hobbes produced works of philosophical character, which, while affording a stimulus to thought, brought him into serious difficulty. He was accused of heterodoxy, and even atheism. But, though he submitted to the Commonwealth, he died a Royalist pensioner.

Hofman, August Wilhelm von
b. Giessen, Germany, April 8, 1818. d. Berlin, May 5, 1892.

One of the greatest chemists of the last century, as a young man he was appointed first director of the Royal College of Chemistry in London. He was brilliantly successful. All the future great chemists of his day came under Hofman's influence. It was by one of his pupils that the aniline dyes were discovered. In spite of all his success, his efforts met with no reward in England. Englishmen did not believe in science in commerce. He, therefore, returned to Germany, and gave his native country the secret of the great coal-tar industry, which has been productive of incalculable wealth to her.

Hogarth, William
b. London, Nov. 10, 1697. d. London, Oct. 25, 1764.

Our great satirist upon canvas was apprenticed to a silversmith, but learned drawing in the school of Sir James Thornhill, with whose daughter he eventually eloped. His work as an artist seriously began with illustrations of "Hudibras." Portraits followed, and then the series of cartoons pillorying the vices of his time. His power as a humorist was great; but he was still more a preacher on canvas. Many of Hogarth's drawings are coarse and unlovely, but so were the subjects he attacked.

Hogg, James
b. Ettrick, Selkirkshire, 1770. d. Eltrive Lake, Yarrow, Nov. 21, 1835.

Receiving less than a year's education, this delightful poet became, at seven years of age, a shepherd-boy, and lives in history as the Ettrick Shepherd. It was while working as a shepherd that he was granted access to books which enabled him further to educate himself. Then meeting "a half daft man," who recited some of Burns's poems to him, and said that they were by the sweetest poet that ever was born, Hogg determined that he would make an effort to fill the dead singer's place. His work attracted the attention of Scott and Byron, and both helped him, as did the Countess of Dalkeith. The latter left him a farm at a nominal rent, and he farmed and wrote poetry to the end of his days. Some of his work is exquisitely dainty, and it has been justly said that at his best he might have claimed over all his contemporaries the laurel for direct and immediate inspiration.

Holbein, Hans
b. Augsburg, Bavaria, 1497. d. London, 1543.

He was called Holbein the younger, to distinguish him from his father, who also was a skilful artist, and was his master in painting. Holbein's early manhood was spent partly on the continent, partly in England. Here he painted the portraits of Erasmus, Anne of Cleves, Sir Thomas More, and Henry VIII. He died of the plague upon a date unknown.

Holberg, Ludvig von
b. Bergen, Norway, Dec. 3, 1684. d. Copenhagen, Jan. 28, 1754.

The father of the Danish drama and the greatest figure in Danish literature, he was a man of versatile genius. In addition to his plays, he wrote satires, history, biography, as well as serious reflective works. He also held important academic rank at the Copenhagen University.

Holden, Sir Isaac
b. Burlet, Renfrewshire, May 7, 1807. d. Keighley, Yorks, Aug. 13, 1897.

He was the son of a collier, who, though a poor man, did the best he could for his boy's education. The boy himself was studious, and though a great part of his early days was spent in the factory, he managed so well to equip himself with knowledge that he became a school teacher. While acting in this position he discovered the principle of the lucifer match, though—unknown to him—a Stockton chemist had been before him. His greatest triumph, however, was won in connection with the wool-combing machinery which he invented. This brought great wealth to him and to all associated with him in the business. He was made a baronet four years before his death.

Holinshead Raphael
b. Cophurst, Cheshire. d. Braincote, Warks, 1580.

The author of the famous "Holinshead Chronicle," giving the history of England, Scotland, and Ireland down to his own era, had assistance in his great work, but he was responsible for the enterprise. The work is of great importance to historians, and additionally interesting to us all, from the fact that from this "Chronicle" Shakespeare drew the material for his early English plays.

Homer
Lived about 9th century B.C.

No fewer than seven towns in Greece claim to be the birthplace of Homer, the father of poetry, but no authentic record on the subject exists. Nothing is known of the poet himself; even the story that he was blind and a beggar is a legend. The two great epic poems which we call Homer—the "Iliad" and the "Odyssey"—form one of the most priceless bequests which have come down to us from ancient Greece. It is impossible to determine whether the whole work is by one hand. Both are noble poems, but the differences in general tone and style between the two lead the critics to believe that the "Odyssey" may have been by an unknown later poet, or by one poet welding into a harmonious whole the efforts of a school of poets. It is unlikely that we shall ever approach any nearer to a solution of the mystery. We have the works, and in them Homer, one man or twenty men, lives immortal—the great Greek of Greeks, as Ruskin says—the more notable because of his influence on Virgil, and, through him, on Dante, and all the after ages.

Hood, Samuel, Viscount
b. Butleigh, Somerset, Dec. 12, 1724. d. Bath Jan. 27, 1816.

The son of a clergyman, Samuel Hood entered the Navy as a captain's servant, served as an able seaman, and gradually worked his way up to the rank of admiral. He had a conspicuous place in the sea battles of his time, and, in the words of Nelson, who served under him, was "the best officer, take him altogether, that England has to boast of." He was created a viscount, and made Governor of Greenwich Hospital.

Hood, Thomas
b. London, May 23, 1799. d. London, May 3, 1845.

"He sang the Song of the Shirt" is the epitaph on Hood's tombstone. If he had written nothing else, his days would have been justified. But in grave vein or gay he was always writing, though his health was of the worst, and his fortunes often dismal in the extreme. A business misfortune consumed all his possessions, but he was too honourable to declare himself bankrupt; he mortgaged his brain to work off his liability, and broke down while still at his task. Hood began his career in a merchant's office, and was afterwards apprenticed to an engraver, but was too delicate for the work of either position.

Hooke, Robert
b. Isle of Wight, July 18, 1635. d. London, March 3, 1703.

One of the greatest of experimental philosophers, Hooke anticipated the invention of the steam-engine and of the flying-machine, and made material contribution to mechanics in the direction of ingenious contrivances for clocks and watches. He carried further the scientific manufacture of optical instruments, and afforded Newton valuable assistance in his theory of gravitation. He was delicate and eccentric, but a good man, and very industrious; he earned his place in history as the most notable of philosophical mechanics.

Horace, Quintus Horatius Flaccus
b. Venusia, Italy, Dec. 8, 65 B.C. d. Rome, Nov. 27, 8 B.C.

He was the son of one who, once a slave, had as a freeman attained to means, and was able to give him a sound education. He was a student in Rome at the time of the assassination of Cæsar. Horace took arms under Brutus, and fought as an officer at Philippi. Returning to his home, he found his property confiscated, and himself driven to write verses for a living. Thanks to the friendship of Virgil, he came to enjoy the patronage of Mæcenas, who presented him with a pretty property in the Sabine Hills. Here the greater part of his years were spent, and here were written the famous satires, epistles, odes, and lyrics by which he immortalised himself.

Howard, John
b. London, Sept. 2, 1726. d. Kherson, Russia, Jan. 20, 1790.

A personal experience made Howard a prison reformer. He was on a voyage to Lisbon when captured by a French privateer, and thrown into prison at Brest. The horrors of a fortnight's detention led him, upon his return to England, to inquire into the condition of English prisons. From that time his life and fortune were devoted to the cause of the reform of our gaols. He died while on a tour of inspection in Russia, killed by typhoid fever.

Huber, François
b. Geneva, July 2, 1750. d. Geneva, Dec. 31, 1831

He worked with such assiduity in the pursuit of knowledge that by the age of fifteen he had begun to lose his sight, and eventually became totally blind. But the noble woman to whom he had become engaged married him in spite of his blindness, and was sight to him. Together they made the bee their life-study, and laid the foundation of all our scientific knowledge of the fascinating subject.

Hugo, Victor Marie
b. Besançon, France, Feb. 26, 1802. d. Paris, May 22, 1885.

His father was a general in the army of the Empire, and carried his family with him, as far as possible, to the various places in which he was quartered. Hugo was a phenomenon as a boy – there can never have been another such. Between his thirteenth and sixteenth years he had written every possible kind of verse odes, satires, epistles, poems, tragedies, elegies, idylls, imitations of Ossian, translations from the classics, romances, fables, stories, epigrams, madrigals, logographs, acrostics, charades, enigmas, impromptus, and a comic opera. And yet this boy was destined by his father for a military career! The Academy withheld the prize which he had won for a poem, believing it impossible that the author was only fifteen years of age. His example, Mr. Swinburne has said, will stand for ever as the crowning disproof of the doubtless more plausible opinion that the most amazing precocity of power is a sign of ensuing impotence and premature decay. The boy, in this instance, was father of the man. His literary activity was unbounded. He took his share in the public life of France of his day, and helped to administer the affairs of the country. Napoleon fired his imagination, but the coup d'état of Napoleon III. filled him with indignation, and France and Belgium became successively impossible as places of residence. He retired to Guernsey, where his literary outpourings proceeded unchecked. The fall of the Second Empire recalled him to Paris, where he remained throughout the Commune, but, retiring again to Brussels, was again expelled the kingdom. Paris once more opened her arms to him, and made him a Senator. Almost to the end of his long life he continued to write, and though towards the close of his career he fell below the high standard of his earlier work, his record is almost without parallel for variety of themes and treatment, for nobility of aim and beauty of expression. He has been acclaimed the finest purely literary spirit that France has ever produced.

Humboldt, Friedrich Heinrich Alexander
b. Berlin, Sept. 14, 1769. d. Berlin, May 6, 1859.

As a child he was called "The Little Apothecary," so keen was his devotion to scientific subjects. At twenty he had matured his powers, and resolved upon the career of scientist and explorer. All his studies were directed to that end. He travelled through Europe, spent some years as a mining engineer, resumed his European travels and studies, then made a productive exploring trip to Mexico and South America. For the next twenty years he resided mainly in Paris, engaged in scientific pursuits, then went to Berlin, whence, at the invitation of the Emperor of Russia, he departed on an expedition to Siberia and the Caspian Sea. The monumental results of his investigations were given to the world in thirty volumes of brilliant writings. He found time to discharge numerous important political missions, and was not less esteemed as a diplomatist than as a great master of learning, the Encyclopædia of Science, as Emerson has named him.

Hume, David
b. Edinburgh, April 26, 1711. d. Edinburgh, Aug. 25, 1776.

The famous historian and metaphysician "found himself," after expeditions in various directions in search of a vocation. He first tried the law, then commerce, was at various times companion to men of note, Under-Secretary for the Home Office, and Judge-Advocate. He had attained his forty-first year when he decided to write his "History of England," and completed it nine years later. His political and moral essays, though not invariably attracting great attention at the time of publication, have since had a decided effect upon the opinion of the country.

Hunt, William Henry
b. London, March 28, 1790. d. London, Feb. 10, 1864.

The father of English water-colour drawing was a puny cripple, son of a journeyman tinplate worker. His gift for drawing was inexplicable. It showed itself when he was quite young, and he was soon copying Gainsboroughs at eighteenpence apiece. A good-natured patron of art took him in hand, and gave him an introduction to the Earl of Essex, the interior of whose house formed the subject of Hunt's first picture at the Royal Academy. Ruskin places him among the greatest colourists of this country. He left a fortune of over twenty thousand pounds, all earned by his brush.

Hunt, William Holman
b. London, April 2, 1827.

With Dante Gabriel Rossetti, Millais, and other artists he founded the "Pre-Raphaelite" school of painting, which aims at telling the truth, the whole truth, and nothing but the truth in a painting. The most famous of all his many well-known pictures is "The Light of the World." The original is in the chapel of Keble College, Oxford; a replica has been sent by Mr. Charles Booth on exhibition throughout the British Empire.

Hunter, John
b. Long Calderwood, Lanarkshire, 1728. d. London, Oct. 16, 1793.

Destined to become the founder of modern scientific surgery, Hunter wasted his youth, and never quite made good the opportunities neglected. Spelling and grammar were always too much for him, yet he was the instructor of the great surgeons who were to follow him. He disregarded books, and studied instead men, animals, and plants. His discoveries were of the greatest importance to the science of which he became the chief exponent. All the money which he could spare he devoted to the collection of specimens which, when catalogued years later by Owen, formed a priceless possession to comparative anatomists. Hunter's wife was the author of

"My mother bids me bind my hair," and other popular poems. Among his pupils were Jenner, Astley Cooper, and Abernethy. William Hunter, another great surgeon, was his brother, and gave his more famous junior his first insight into surgery.

Hunyadi, Janos
b. Hunyad, Transylvania, 1387. d. Somlin, Croatia-Slavonia, 1456.
A great Christian general, he was Regent of Hungary during the minority of Ladislaus V. His whole career was one long campaign against the Turks, whom he defeated in many brilliant battles. His most famous achievement was the storming of Belgrade.

Huss, John
b. Prachatitz, Bohemia, July 6, 1369. d. Constance, Baden, July 6, 1415.
His preaching of Wyclif's tenets brought him under the ban of the Roman Catholic church. The Pope by bull condemned Wyclif's teachings, but Huss continued to expound them, was brought to trial, refused to recant, and was burnt at the stake. The Hussite war, which followed, was the outcome of the resistance of his followers offered to the whole forces of the Empire, and sustained for a generation at terrible cost in lives to both sides.

Hutton, James
b. Edinburgh, June 3, 1726. d. Edinburgh, March 26, 1797.
The son of well-to-do parents, he received an excellent education, and was then placed in the office of a lawyer. But his mind from the outset ran wholly on science, and when he should have been studying lawyers' laws, he was probing Nature's. His articles were cancelled, and he was sent to Paris and Leyden to study medicine. This, too, he abandoned, and determined to try scientific farming, which conducted him to mineralogy and geology, in which his interests really lay. His laborious researches led to his discovering the modern explanation of the phenomena of the earth's crust by means of changes still in progress. The "Huttonian Theory" was assailed by his contemporaries, and it was not until the luminous exposition of John Playfair made the ponderous tomes of the founder of geology popular that the significance of Hutton's discoveries was realised. He had no mathematical knowledge, and went astray in adopting the phlogiston theory; but, with every detraction considered, the value of his work remains very high.

Huxley, Thomas Henry
b. Ealing Middlesex, May 4, 1825 d. Eastbourne, June 29, 1895.
The seventh child of a seventh child, Huxley began his education under his father, who had the future Cardinal Newman among his students. For the son of a school teacher, his education was strangely desultory and irregular. "I had two years of a pandemonium of a school between eight and ten—and after that neither help nor sympathy in any intellectual direction till I reached manhood," he recorded. His desire was to be a mechanical engineer, but the study of Hutton's works, of logic, and of German, and the fact that two of his sisters married doctors, fortunately led to his taking other paths. He was apprenticed to a London surgeon, and at his first post-mortem examination contracted an illness which left him with chronic dyspepsia. In his twentieth year he announced an important discovery in relation to the human hair. In the same year he graduated M.B., and won a gold medal for anatomy and physiology. Like Darwin, he was destined to find fame on the sea. He took voyages, in the capacity of assistant-surgeon, in two ships, and in both made important contributions to the science of biology. His fame was now growing, but he had no funds with which to publish the full results of his work. Ordered to rejoin his ship, he had to throw up his only certain income rather than leave unfinished the work of completing the description of his collection of specimens. Fortunately, the position of lecturer on natural history at the Royal School of Mines fell vacant at an opportune moment, and Huxley was appointed. He was now in a position in which he could make his influence felt. Despite lasting ill-health, he addressed himself with heroic energy to the popularising of science. In the great controversy on evolution he played a leading part in support of Darwin. His lectures to his students, to unscientific audiences, and especially to working men became famous. Honours crowded upon him, and no man of science of his era had greater influence. He was one of the first members of the London School Board, and accomplished much for the improvement of popular education. His writings and lectures on scientific and philosophical subjects are by this time for the most part classics. The nineteenth century produced few such splendid brains as Huxley's, few men so strong and courageous and lovable withal.

Huygens, Christian
b. The Hague, Holland, April 14, 1629. d. The Hague, July 8, 1695.
He was the son of a poet and diplomatist, whom James I. knighted, and studied physics, astronomy and mathematics at Leyden University. One of his greatest advantages was his adaptability. He could seize upon and improve a new idea. Thus he invented the pendulum clock, on the suggestion of Galileo; and, developing the same philosopher's theory of the acceleration of motion under the influence of gravity, prepared the way for Newton. Huygens, who first expounded the undulatory theory of light, discovered Saturn's ring and one of his satellites.

Hypatia
b. Alexandria, fourth century A.D. d. Alexandria, fifth century.
The daughter of an Alexandrian astronomer and mathematician named Theon, she learned all that her father could teach her, then went to Athens, where she became so proficient in philosophy that she returned to Alexandria to become noted herself as a teacher. She presided in the public schools, teaching philosophy and mathematics. Her beauty and talent made her very famous, and excited the hatred of a bigoted Christian archbishop, one of whose creatures headed a riot in the course of which she was stripped of her clothing and torn to pieces in the public streets. Kingsley's novel is founded upon her career.

Ibsen, Henrik
b. Skien, Norway, March 20, 1828. d. Christiania, May 23, 1906.
The failure of his father's fortune coloured the early life of the future poet and dramatist. He was apprenticed to an apothecary, but studied literature in his leisure, and before he was twenty-one published his first work. It was a failure, as were several others—dramatic and poetic. He had tried his fortune in journalism and as manager of a theatre before he gained the approving attention of the world with the plays which made him famous. "Love's Comedy," written in his thirty-sixth year, linked his name with the social and satirical drama, and the future held no more difficulties for him, though his works were never received without prolonged and bitter controversy. Ibsenites see in him the stern moralist depicting conditions and life as they are; his critics find him morbid, and a painter of things which ought not to be painted.

Ivan III.
b. Moscow, 1440. d. Moscow, Oct. 27, 1505.
Ivan the Great, as he is commonly called, was born Grand Duke of Moscow. Finding the country divided into many petty states, and tributary to the Mongolian Tartars, he made Russia a whole, and became the first Tsar and founder of the Russian Empire. Ivan the Terrible (b. 1530; d. 1584) was an enlightened but cruel and

barbarous prince, who slew his own son in a fit of passion. He extended the dominion of Russia—notably by the acquisition of Siberia. By him the first printing press was established in Russia, and the mission sent to England by which the first treaty between Russia and this country was signed.

Jacquard, Joseph Marie
b. Lyons, July 7, 1752. d. near Lyons, Aug. 7, 1834.

The inventor of the famous silk-weaving loom which bears his name was the son of poor parents, and while pursuing his experiments had to sacrifice everything he possessed to carry on his work. He was unsuccessful, and became a labourer, then a soldier. It was not until he had entered his fiftieth year that the fame of his invention became public. Even then he still had years to wait before it was perfected. The workpeople of Lyons fiercely resisted its introduction, but he lived to see it in universal use.

Jenner, Edward
b. Berkeley, Glos., May 17, 1749. d. Berkeley, Jan. 26, 1823.

The discoverer of vaccination for smallpox was a son of the rectory. He was twenty-six when he began his investigations, but twenty years had elapsed before the medical faculty accepted his theory. His own hope was that by the universal application of vaccination smallpox would become extinct. He was rewarded by two Parliamentary grants, aggregating £30,000.

Joan of Arc
b. Domremy, France, Jan 6, 1412. d. Rouen, May 30, 1431.

"The Maid of Orleans" was the daughter of peasants. She never learned to read or write, but was characterised by boundless mental and physical activity. At this time the English were masters of the whole of France north of the Loire, and Henry V. of England had been proclaimed King of France. A local saying that France was to be redeemed by a virgin out of the forest of Domremy seems to have impressed the mind of the girl. Although she was devoted to her parents, and received with reverence the spiritual instruction of her mother, she dwelt apart, as it were, and dreamed of the prophecy, until she fancied that she heard supernatural voices declaring that she was the maid appointed to the task. She eventually gained access to the Court of Charles VII., and persuaded him to give her the command of an army. At the head of this force she was brilliantly successful. She raised the siege of Orleans, drove the English from their principal position on the Loire, and had the king crowned at Rheims. Still continuing her campaign against the invaders, she was eventually captured by the English at Compiègne—sold, it is said, by traitors for 10,000 crowns. Arraigned before a spiritual tribunal at Rouen, she was condemned as a heretic, and, according to a version upon which later research casts doubt, burnt at the stake.

Johnson, Samuel
b. Lichfield, September 18, 1709. d. London, Dec 13, 1784.

Johnson owes immortality to his disciple and biographer Boswell. The great literary dictator of his age would not be known to posterity as the man he was but for his faithful henchman, who mirrored his manners, ideas, and diction in a manner which Johnson in his own writings quite failed to do. He was the son of a second-hand bookseller, afflicted, in spite of great physical strength, with a disease for which he was "touched" by Queen Anne. In spite of his prodigious mental activity, he failed to obtain a degree at Oxford during his years of residence. He made two or three attempts as a schoolmaster, but without success, and came to London, accompanied by a pupil, David Garrick. He had already married a widow, whose small fortune a calamity soon absorbed. During many years his life in London was one long struggle with adversity. He was still very poor when he projected his famous dictionary. The publisher agreed to pay him £1,575 for the entire work. To complete it he had to employ six amanuenses, five of whom were Scotsmen, whom he affected so heartily to despise. The dictionary was dedicated to Lord Chesterfield, whose discourtesy and neglect were noted in a letter which has become famous. During the latter portion of his life, Johnson enjoyed a Government pension of £300 a year, and became the centre of that literary circle which Boswell has rendered famous. He had no taste for music or pictures; he had many prejudices, and was dogmatic, and apt to browbeat those who crossed him. But, withal, he was one of the greatest figures of his age—a noble-hearted, lovable man, whose wise and witty sayings are to this day in all men's mouths.

Jones, Inigo
b. London, July 15, 1573. d. London, June 21, 1652.

Like many another genius, this great architect began his career in unpromising circumstances. His father was so poor that he was compelled to pay a debt by instalments so small as ten shillings a month. The boy was apprenticed to a carpenter, but his aptitude for drawing attracted the attention of the third Earl of Pembroke, who sent him to Italy to study. He is said to have designed a palace during this trip for the King of Denmark. His first work of note in England was to design the scenery and machinery for the presentation of plays by Ben Jonson and other dramatists. Following this came his appointment as Surveyor-General, and the beginning of his architectural work. His banqueting-house in Whitehall was intended as part of an immense palace. His Lincoln's Inn Chapel, his residence for the Queen at Greenwich, and many other notable buildings in the capital and the country, caused it justly to be said that "what was truly meant by the art of design was scarcely known in this kingdom until he brought it into use and esteem amongst us here."

Jonson, Benjamin
b. London, 1573. d. London, Aug 16, 1637.

One of the most celebrated poets and dramatists, he was the posthumous son of a clergyman. His mother marrying a bricklayer as her second husband, the boy was taken from school, and put to work at his stepfather's trade. His spirit revolted against it and he fled, to join the Army as a private soldier, and serve bravely in a campaign in Holland. Returning to England, he got himself entered at St. John's College, Cambridge, but was forced back to London, to earn his bread as author and actor. A duel with a brother actor terminating fatally for his antagonist, Jonson was imprisoned, and narrowly escaped execution. At twenty-four he published his famous play, "Every Man in His Humour," and thereafter produced a play annually for several years, in addition to masques and smaller pieces for the Court. His share in a dramatic piece which Court favourites resented nearly cost him his nose and ears, which he was condemned to lose in the pillory. He soon regained the Royal favour, and was appointed Poet Laureate, and, following journeyings on the Continent, was the recipient of an honorary degree from Oxford University. But his health was now impaired, and he died of palsy, and was buried in Westminster Abbey, with the simple epitaph, "O, Rare Ben Jonson." His dramas exhibit pungent humour and profound philosophy. They are unequal, as are his poems; but while Shakespeare is accounted among the gods of English verse, Jonson is in the forefront of the giants. Some of his songs are for all time. In spite of his poverty and hard youth, he was among the most learned men of his age.

Josephus, Flavius
b. Jerusalem, 37 A.D. d. Rome, second century A.D

The great Jewish historian was the son of a priestly house, and so early profited by educational advantages that he was frequently consulted as a youth by the high priests and prominent citizens

upon points of Jewish law. After three years in the wilderness as the pupil of a hermit, he went to Rome. His visit impressed him with the power and resources of that empire, and upon his return he did all he could to dissuade his countrymen from their contemplated rising. His voice was not heeded. He himself was swept into the revolutionary movement, and held important military commands until defeated and taken prisoner by Vespasian. The latter befriended him, and upon becoming emperor gave him a residence in Rome. Here Josephus produced his immortal literary works.

Juvenal, Decimus Junius Juvenalis
b. Aquinium, Italy, first century A.D. d. about 140 A.D.
Little is known of the life of this celebrated Roman satirist. He was the son, either by birth or adoption, of a wealthy freedman, who gave him a liberal education. Half his career was spent at the Bar, where he acquired considerable reputation. Against his will he was sent to Egypt, and resided afterwards for some time at his native place. His immortal satires were directed against the social vices of the early Roman Empire, and underlying them all is a strong dislike of the imperial regime, and regret for the loss of the old Republican system. Dryden's translations of Juvenal are among his finest work.

Kant, Immanuel
b. Königsberg, Germany, April 22, 1724. d. Königsberg, Feb. 12, 1804.
The son of a poor saddler of Scottish stock, he studied at the local university, and never resided away from his native city. He was successively private tutor and university lecturer. He lectured on logic and the various branches of metaphysics, on anthropology, physical geography, and mathematics. His great work, the "Critique of Pure Reason," was twelve years in preparation. It was only during the last twenty years of his life that he was famous, though he had published several treatises, in one of which he predicted the existence of Uranus, which Herschel afterwards discovered. His fame spread throughout Europe as work after work followed his "Critique," and an enormous impulse was given by his labour to critical philosophy, of which he was the founder.

Kay, John
b. near Bury, Lancs., July, 16, 1704 d. France, after 1764.
The inventor of the "fly shuttle" was twenty-nine when granted a patent for this extremely important invention—perhaps the most important improvement ever made in the loom. His patent was unblushingly infringed by the manufacturers of his day, and the costs of litigation almost beggared him. His brain teemed with schemes for further improvements in industrial machinery, but the mob broke in and destroyed everything he possessed. He fled to France, and there died in obscurity and poverty. British industry owes an enormous debt to this poor fugitive, who starved to death in a foreign land.

Keats, John
b. London, Oct. 31, 1795. d. Rome, Feb 23, 1821.
This rare and great genius was the son of an ostler, who had married the daughter of his employer, a livery-stable keeper in Moorfields, London. The poet was born in the house adjoining the stables, and went to school at Enfield, where, after two idle years, he applied himself with extraordinary enthusiasm to the study of literature, of which classical mythology was his favourite. He carried from school some Latin and French, but no knowledge of Greek in the original. Keats inherited a modest competence from his grandfather, a practical old man, who apprenticed him to an Edmonton surgeon. The work did not appeal to the poet; and though he studied for three years at the London hospitals, he withdrew at the earliest possible moment to devote himself to the muse, encouraged by the example, if not advice, of his literary friends, among whom were Shelley and Leigh Hunt. "Endymion," though not free from fault, contains so many beauties that it was hailed with acclamation by all but the terrible "Blackwood" and "Quarterly," which attacked it with characteristic ferocity. He bore the onslaughts bravely, but they left an ineradicable scar. The last volume contains some of his finest work, but his health was broken. His devotion to a sick brother, the fatigues of a walking tour in Scotland, and his passionate love for a woman who did not appreciate him, rendered his condition critical. He went to Rome, and died three months after arrival. He had many friends, one of whom—Severn the artist—accompanied him to Rome, and tenderly nursed him until he died.

Keble, John
b. Fairford, Glos., April 25, 1792. d. Bournemouth, March 29, 1866.
The "sweet singer of Israel" and true saint, as Mr. Gladstone called him, was an Oxford professor and a clergyman. With him originated the Tractarian Movement, culminating in the famous "Tract No. 90." His "Christian Year" is the most famous of his poetical writings. Keble College, Oxford, was erected to commemorate him. It is for students of limited means.

Kelvin, William Thompson, Lord
b. Belfast, June 26, 1824.
His father was Professor of Mathematics in the University of Glasgow, where, at the age of twenty-two, young Thompson was to begin a professorship of natural philosophy which was to last over half a century. Meanwhile, he much distinguished himself at Cambridge University. Not only was he a brilliant student, he was famous as an oarsman. At seventeen he attracted the attention of scientists by a brilliant paper on heat and electricity, which showed quite original method of investigation, and was destined to be of importance to subsequent investigations. Since then his writings on science have been beyond enumeration, and their effect upon the scientific learning of the age above comparison. His inventions are of equal importance. It is by those in the field of telegraphy, and those which form aids to navigation, that he is best known to the public. His share in the Atlantic cable brought him a knighthood; his inventions of the magnetic compass and of his famous sounding-machine, which enables the depth of water to be taken without a ship slackening speed, make his name a household word with sailors. His researches in electrostatics gave us those infinitely fine instruments which embody the perfection of mechanical and geometrical adjustment. He has received all the distinctions possible to a man of science, and his jubilee at Glasgow University drew together a notable gathering of British and European scientists.

Kempis, Thomas à
b. Kempen, Germany, about 1379. d. Zwolle, Holland, July 25, 1471.
His real name was Thomas Hamerken; that by which he is known comes from his birthplace. He was trained in an Augustine convent near his native town, and became eventually its superior. Of all his writings, the "Imitation of Christ," of which he is believed to be the author, is the most famous. No other book, after the Scriptures, has been so often reprinted; none other translated into so many languages. A copy of the work—not the first—in the handwriting of Thomas himself is to be seen in Brussels.

Kepler, Johann
b. Weil, Germany, Dec. 27, 1571 d. Ratisbon, Germany, Nov. 15, 1630.
He was the son of poor gentlefolk, and himself scarcely ever free from domestic worries. His first appointment was that of mathematical lecturer at Grätz, he not having as yet taken any interest in astronomy. Fortunately, he was brought into communication with Tycho Brahé, who directed his studies to the work with which he was to immortalise himself. After labouring for some time with Tycho, Kepler succeeded him as

astronomer to the Emperor Rudolf, and at the death of the older man inherited his vast store of facts, as he had benefited by all that he had learned of him. The publication of his famous astronomical laws formed the basis of Newton's work, and the foundation of modern astronomy.

Kingsley, Charles
b. Dartmoor, June 12, 1819. d. Eversley, Hants, Jan. 23, 1875.
The son of a clergyman, Kingsley, after a successful course at Cambridge, took orders, though at one time he had such religious doubts that he declared his intention of quitting the University for the prairies. He first became curate, then rector of Eversley, interested himself in Christian Socialism, and became one of its most powerful exponents. His earlier novels, written with this purpose in mind, excited extraordinary interest. Under the pen-name of "Parson Lot" he wrote a great number of articles for the Press, further elaborating his doctrines. The latter he put into practice in his daily intercourse with his own flock. He held two professorships, and was made Canon of Westminster and chaplain to Queen Victoria. Miss Mary H. Kingsley was his niece. His second daughter, who in 1876 married the rector of Clovelly, but has since become a Roman Catholic, is the well-known novelist "Lucas Malet."

Kipling, Rudyard
b. Bombay, Dec. 30, 1865.
Inheriting talent from both sides of his family, he was sent home to Westward Ho for his education, then, returning to India, was put to work on a newspaper. The short tales which were later to make him famous were written for the paper with which he was associated, and accepted as additions to routine work not willingly, but as a favour to the author. These he eventually put into book form, issuing them one at a time in slim, paper-backed volumes. They made his name at once in India, and later in England. Since then he has travelled almost as far as his fame. He married an American lady, and nearly died in the land of her birth in 1899. The "Bard of Empire," as he is called, he is also the laureate of the barrack-room. His noblest composition—one which, whatever befall the rest, is sure of immortality—is his grand and splendid "Recessional," written for the Diamond Jubilee.

Kircher Athanasius
b. Geisa, Germany, May 2, 1602. d. Rome, Nov. 28, 1680.
Although he was a great scholar and mathematician, Kircher, who was professor first at Wurzburg of philosophy, mathematics, and Oriental languages, then of mathematics at Rome, is best remembered as the inventor of what is still popularly termed the magic-lantern.

Klopstock, Friedrich Gottlieb
b. Saxony, July 2, 1724. d. Hamburg, March 14, 1803.
The founder of modern poetry in Germany was educated at his native Quedlingburg, at Jena, and at Leipsic. Inspired by Milton, and, to a lesser extent, by Virgil, he published three cantos of his sacred epic, the "Messiah." This at once brought him favour and fortune. The completion of his epic occupied him nearly thirty years. It has been superseded by far nobler works, but its influence in creating a German poetic literature can never be overlooked.

Knox, John
b. Haddington, 1505. d. Edinburgh, Nov. 24, 1572.
The perfect symbol of Reformation in all countries and times, as Ruskin has called him, was first a lawyer in Glasgow, where he was educated at the university, then a priest of the Roman Catholic Church. He next became a tutor, and was brought in touch with a Lutheran reformer, by whom his religious opinions were much influenced. This man, Wishart, was burned at the stake for heresy. His death was avenged by the murder of Cardinal Beaton, whose assassins held the castle in which the crime was committed, and called thither Knox, who was now formally admitted to the ministry. St. Andrews yielded to the French, and Knox was confined to the galleys for eighteen months. Upon his release he travelled and preached in England, was made one of the chaplains to Edward VI., and assisted in the reformation of the second Prayer Book. On the accession of Mary Tudor he fled to the Continent, and came under the influence of Calvin. His "Blasts of the Trumpet Against the Monstrous Regiment of Women" was first directed against Mary of Guise, then Regent of Scotland, against Mary of England and Catherine de Medici, but it complicated his relations with Mary Stuart. When the latter, as widow of the Dauphin, returned to Scotland, the battle between herself and him at once began, and led to the dramatic interviews which have become famous. In the end, thanks mainly to his efforts, Roman Catholicism was abolished in Scotland. The times in which he lived were violent, and the cause which he made his own was endangered by many terrible deeds by his disciples. He himself was rough and rude at times, but the verdict of history upon his life, his acts, and his writings is that no one in England or Scotland who values liberty—national, civil, or religious—can speak of John Knox without reverence and gratitude.

Koch, Robert
b. Klausthal, Germany, Dec. 11, 1843.
It was while practising as a physician that he began those researches in bacteriology which have made him famous. His investigations as to anthrax, Asiatic cholera, rinderpest, and bubonic plague have led to important results. Controversy still rages round the conclusions which he has reached on the subject of tuberculosis.

König, Friedrich
b. Eiselben, Germany, April 17, 1774. d. Jan 17, 1833.
Trained to the trade of a printer, he devoted his leisure to planning a steam press. This, with the assistance of Bensley, a London printer, he was able, in 1810, to patent. In the following year he obtained a patent for a cylinder press, which, in improved form, was adopted three years later for the printing of the "Times."

Lagrange, Joseph Louis de
b. Turin, Jan. 25, 1736. d. Paris, April 10, 1813.
Interested at first in literature rather than mathematics, he eventually devoted himself to his calculus of variations, which had highly important results for the higher branches of physical astronomy. He was for twenty years a professor at Berlin, on the invitation of Frederick the Great; but, turning to Paris, was received with honours and emoluments, to devote the rest of his days to the dissemination of knowledge in the French capital.

Lamarck, Jean Baptiste Pierre Monet de
b. Bazentin, France, Aug. 1, 1744. d. Paris, Dec. 18, 1829.
The founder of invertebrate zoology was for some years in the French Army, from which his retirement was necessitated by an injury. He became bank clerk, studied medicine, and then botany. Securing an appointment at what has since become the Jardin des Plantes, on the creation of the museum, he became responsible for the lowest order of animals, what Linnæus had called merely insects and worms. These he reclassified into ten classes, and, though his work has been superseded by subsequent labourers in the same field, its importance at the time was very great. His researches led him to the theory that altered conditions of life lead to variation of species. He was the forerunner in this matter of Darwin and his school.

Lamb, Charles
b. London, Feb. 10, 1775. d. Edmonton, Middlesex, Dec. 27, 1834.
The best-loved personality in English literature was the son of a man who had graduated from domestic service to the position of clerk to a

wealthy Bencher of the Temple. He was entered at Christ's Hospital—the Blue Coat School—where Coleridge, his lifelong friend and first collaborator, was also a pupil. Lamb became a clerk in the South Sea House, and afterwards in the India House. When he was twenty-one his sister Mary, in a fit of madness, murdered their mother. Thereafter he became her constant guardian, devoting his life to her care. In her lucid intervals she wrote; the comedies in their joint "Tales from Shakespeare" are hers. His early poems were inspired by an attachment which the care of his sister caused him to renounce. His famous essays—the "Essays of Elia"—were begun when he was forty-five, and appeared in "The London Magazine." The name under which he wrote was that of a former clerk in the India House. He enjoyed the friendship of all the literary men of his age, and was recognised as a critic and humorist of the highest order. When, after a generation spent in the service of the India House, he retired on a pension of £450 a year, he went with his sister to Edmonton. His term of rest was not more satisfactory to him than the condition of retirement which he describes in one of his essays. His sister Mary was all her life subject to fits of insanity, and these became more frequent and of longer duration as age increased. His last days were thus saddened by this grief, and also by the loss by death of many of his dearest friends. In life he was the same gentle, merry, tender-hearted, delightful man which his writings suggest, and his position in the affections of posterity can never be assailed.

Landseer, Sir Edwin Henry

b. London, March 7, 1802. d. London, Oct. 1, 1873

The youngest of a talented brotherhood, Landseer was the son of an engraver, who early taught his son the art of drawing from life. When he was yet in his fourteenth year he exhibited a picture at the Royal Academy, while at sixteen he became famous with the picture "Fighting Dogs." From that time forward he was a regular exhibitor at the Academy, of which he became an associate, then a member, and finally declined the presidency. He attained the very highest rank among animal painters. Deer and dogs and horses were his favourite studies. His one fault was that he gave his animals too human an expression. The noble lions at the base of the Nelson monument in Trafalgar Square are of his execution. He received the commission in 1858, and the figures were finally placed in position in 1867.

Lâo-Tsze

b. 604 B.C., Honan, China. d. China, date unknown.

Although five-and-twenty centuries have elapsed since the birth and death of Lâo-Tsze, his birthplace and the temple erected in his honour are still pointed out. He was for some time one of the keepers of the king's archives, but retired to live a life of quiet and contemplation. He bequeathed to his country the religion which, with Buddhism and Confucianism, still holds sway today. It was the simple and quiet life which he preached. He deprecates learning and recourse to arms, and bids his followers requite injury with kindness. Confucius, who was much his junior, went to see him, and was reproved for troubling himself with the affairs of the world. The teaching of this philosopher is contained in his classical "Book of the Way."

Laplace, Pierre Simon Marquis de

b. Calvados, France, March 28, 1749. d. Paris, March 5, 1827.

The son of a farmer, he became a professor of mathematics, and renowned for his mastery of the whole science of mathematics and its application to practical astronomy. For six weeks he was Minister of the Interior under Napoleon. His contributions to science deal with the tides, with lunar motions, and the nebular theory.

Latimer, Hugh

b. Thurcaston, Leicester, about 1485. d. Oxford, Oct. 16, 1555.

The son of a yeoman farmer, he became Bishop of Worcester. He was one of the divines who found in favour of the divorce of Henry VIII. In his forty-fifth year he was, in his own words, "as obstinate a Papist as any in England." From that time, however, he turned strongly to the Protestant faith. Called upon, after the accession of Mary Tudor, to recant, he declined, and died, burnt at the stake, in company with Ridley, saying, "Be of good comfort, Master Ridley, and play the man. We shall this day light such a candle, by God's grace, in England as I trust shall never be put out!"

Lavoisier, Antoine Laurent

b. Paris, Aug. 26, 1743. d. Paris, May 8, 1794

One of the crimes of the French Revolution was the execution of Lavoisier, the father of modern chemistry. A man of exceptional talent, he first exploded the phlogiston theory of combustion. Until this was dispelled, although Black and Cavendish and Priestley were doing brilliant work, substantial progress could not be made. Lavoisier showed that the true theory of combustion was a process of oxidation. This opened up the way to the correct study of life, by rendering the function of respiration and the production of animal heat for the first time intelligible. This was not his only discovery, but it was the most important, as establishing the basis upon which modern chemistry has been built. He accepted a position as tax-farmer in order that he might have funds with which to carry on his experiments; and, popular rage being excited against all concerned in tax-gathering, he was condemned and guillotined when in the prime of life.

Layard, Sir Austen Henry

b. Paris, March 5, 1817. d. London, July 5, 1894.

He had two careers. One was as member of Parliament and Ambassador; the other, and earlier, was the more picturesque, and is that upon which his fame will rest. He discovered and explored the remains of ancient Nineveh, and made important contributions to our knowledge of Babylon and of the inscriptions on Assyrian monuments by which the history of the Old World is revealed.

Leibnitz, Gottfried Wilhelm von

b. Leipsic, July 6, 1646. d. Hanover, Nov. 14, 1716.

Equally celebrated in philosophy and mathematics, Leibnitz is regarded as having possessed one of the finest minds of his own or any other time. He inherited a bent for philosophy from his father, and was free to pursue his education under the wisest thinkers. With the Elector of Mainz he was engaged in literary and political work. A similar appointment at the Court of Hanover led to his undertaking a history of the House of Brunswick, and the character of his labours entitles him to be regarded as one of the first of the critical school of historical research. He was the inventor of the calculus. It is claimed for Newton that he arrived at the same discovery by independent research. The point was the source of long and acrimonious debate between followers of the two men, but there seems little doubt now that the German was really the pioneer. He visited England, and met the members of the Royal Society, and endeavoured to institute similar bodies in all the capitals of Europe. His discoveries as to the laws of energy, his work in material directions for the better health and comfort of his fellows, his part in the theological discussions of the age, all show the universality of his genius.

Leo I., the Great

b. Rome, about 390. d. Rome, 461.

One of the greatest of the Roman fathers, he was of a good Tuscan family, and during his early manhood was employed in distant missions, which brought him in contact with St. Augustine. He

was called to the Papal chair when absent on one of these errands. He entered with spirit into the duties of his high office, and established a precedent by preaching from his own pulpit. When Attila overran Italy, and had Rome at his mercy, it was Leo who interceded for the capital. He was less successful when the Vandal Genseric invaded Italy. Rome was sacked, but the Pope managed to induce the conqueror to forgo some measure of the conqueror's licence. The remainder of his days Leo devoted to repairing the ruin which the barbarians had wrought. The Roman Empire had fallen, to rise no more; but, thanks to his efforts, Rome now became the spiritual centre of the West.

Leonardo da Vinci
b. Vinci, Italy, 1452. d. Cloux, France, May 2, 1519.

One of the most richly-endowed of Nature's sons, he excelled in art, in sculpture, in all forms of engineering, in music, and in writing. His father was a Florentine notary, who gave him the advantage of study under the greatest masters of the age. But it was as engineer to the Sultan of Cairo that the artist first attracted attention. He resumed the old life years later, when he was appointed to drain the plains of Lombardy, as well as direct the Court pageants. Few of his paintings remain. One, however, "The Virgin of the Rocks," is in the National Gallery, London. His famous "Last Supper," still, after four hundred years and in spite of many restorations necessitated by damp, one of the greatest art treasures in the world, was painted on the refectory wall of the Santa Marie delle Grazie Convent. His most notable sculptural work was the equestrian figure of Duke Francesco of Milan, a colossal and noble statue, which the French destroyed in 1800. Apart from his great subject pictures, he painted many lovely easel pictures; but the student now must rely mainly upon his drawings, of which many authentic collections exist in England and on the Continent. His celebrated treatise on painting was published in 1651.

Le Sage, Alain René
b. Sarzeau, Brittany, May 8, 1668. d. Boulogne, Nov. 17, 1747.

Having failed at the Paris Bar, he turned to literature, and poured out plays, stories, and translations. Most of them were failures. His famous play "Turcaret" was at first rejected. His fame rests upon that and upon his greater work, the immortal novel "Gil Blas." The originality of the work is challenged; his enemies called it a mere conveyance from Spanish sources. But, though the scene and characters are Spanish, the treatment is essentially French, and the result and glory his. He was the first to see the possibilities of the picturesque novel, and later writers of romance owe him an immense debt.

Leslie, Sir John
b. Largo, Fifeshire, April 16, 1766. d. Coates, Fifeshire, Nov. 3, 1832.

The son of a carpenter, he was enabled, by the kindness of the eighth Earl of Kinnoull to study at the University of St. Andrews. Engaged by his friends the Wedgwoods to superintend their studies, he had time for experiment and research, which resulted in the production of a differential thermometer, a hygrometer, and a photometer. Afterwards he travelled much, and conducted inquiries into the nature and properties of heat, with the result that he was the first to announce important discoveries in relation to the radiation of heat. He also first announced the process of artificially freezing water—a discovery of considerable importance. He became mathematical professor at Edinburgh University, and made many notable contributions to the scientific literature of his age.

Lesseps, Ferdinand Viscomte de
b. Versailles, Nov 19, 1805. d. Paris, Dec 7, 1894.

Educated for a diplomatic career, he went, in the course of his profession, as French Consul-General to Alexandria. When he returned, years later, on a visit to Egypt, he unfolded to Said Pasha, the then Viceroy of Egypt, his scheme for the Suez Canal. The project met with fierce opposition, nowhere more severe than in England. In spite of all difficulties, however, the work was carried to a successful conclusion, and to-day England is paramount shareholder in the canal. Honours were heaped upon the engineer, but with his scheme for the Panama Canal came ruin. Enormous sums were involved in the work, and in 1892 he, with five directors, was condemned to imprisonment for breach of trust. He was too ill to undergo sentence, and died at his own house in the following year. De Lesseps was a cousin of the Empress Eugénie.

Leverrier, Urbain Jean Joseph
b. St. Lô, Normandy, March 11, 1811. d. Paris, Sept 23, 1877.

He at first intended to devote himself to chemistry, but a post as teacher of celestial physics was offered to him, and he became one of the greatest astronomers of his age. Certain planetary irregularities led him to investigate the cause. He predicted that the origin of the disturbance would be found in the existence of a then unknown planet. Unsuspected by Leverrier, Adams, the English astronomer, had at about the same time committed himself to a like prediction. Within a few days of the Frenchman's announcement, Galle, of Berlin, actually discovered the planet--Neptune. The two prophets shared the honours of the prediction. Leverrier had a share in shaping the political destinies of France, but it is in astronomy that his fame is established.

Liebig, Justus Baron von
b. Darmstadt, Germany, May 12, 1803. d. Munich, April 18, 1873.

One of the greatest chemists of all time, Liebig claims the gratitude of posterity not only for the immense amount of data which he himself added to the stores of knowledge, but for the enormous impulse to the study and development of chemistry which he gave through the hosts of brilliant students who during two generations sat at his feet. His father was a drysalter, and the boy was fired with a desire to become a chemist from reading old-time experiments. The result of his labours was the foundation of agricultural chemistry, in itself sufficient to make him for all time famous. In addition, he shared in the discovery of chloroform and chloral, and in the extension of the functions of organic and animal chemistry. He invented an extract of beef which has made his name known throughout the world. As professor of chemistry at Giessen and Munich, his lectures attracted students from all parts of the civilised world; and so great was he as a teacher that he trained his sons in science almost to equal him in his own day. His successors, of course, go far beyond the frontiers to which he had advanced, but as a pioneer his work was of incalculable value and merit.

Lincoln, Abraham
b. Kentucky, U.S.A., Feb 12, 1809. d. Washington, April 15, 1865.

The sixteenth President of the United States of America was the son of a backwoodsman, and was born in the wilds of Hardin County, Kentucky. He received an education which could barely be said to comprise the three R's; but he did learn to read. During youth and early manhood he was successively farm labourer, boat-hand, splitter of rails for his father's log hut, salesman in a tiny store of his own which made him bankrupt. Then he began to study grammar and law, and qualified himself for the acceptance of a minor State office, and to contest a seat in the Legislature. He practised law at Springfield, fought in a war against Indians, then resumed his attempts to enter the Legislature. Successful at last, he attracted widespread attention as an unbending opponent of slavery. Finally, in 1858, he was elected, as a Republican, President of the United States. His election precipitated a crisis in the affairs of the nation. The slave-owning states, seeing that an end of temporising had come, seceded from the

Union, so that they might be free to retain their slaves. The North determined that the South should neither retain slaves nor secede from the Union. The result was the most terrible civil war in history. Lincoln, as President, issued a proclamation liberating all slaves. He behaved with courage, fixity of purpose, and diplomacy throughout the war, and had been re-elected for a second Presidential term before the conflict ended. It was while he was occupied with plans for the reconstruction of the devasted South that he was assassinated at a Washington theatre by an actor named Wilkes Booth. He was one of the greatest men America has produced. A sincere Christian, though not attached to any one church, he was truthful, honest, abstemious, a pattern of morality and probity. He was the saviour of his country and the emancipator of a race.

Linnæus, Carl

b. Råshult, Sweden, May 23, 1707 d. Upsala, Sweden, Jan. 10, 1778

The founder of modern botany was the son of a poor clergyman, from whom he inherited his love of Nature. Declining to devote himself to a clerical life, the boy was apprenticed to a shoemaker, but managed to work his way to the Universities of Lund and Upsala, living on £8 a year, and making his own boots from the bark of trees. Luckily, he attracted the notice of a man whose interests were similar to his own, and for the future his path was smooth. When twenty-four, he was sent on an expedition to Lapland, whence he returned with a mass of new material on natural history. Befriended in Holland by Boerhaave, he was given charge of the gardens and collection of a wealthy Haarlem merchant. His career closed with an appointment to a professorship of physic and botany. He devised the system of classification of the animal and vegetable world called, after himself, the Linnæan system, and his grouping has been of inestimable value to succeeding generations of botanists.

Lister, Joseph, Lord

b. Upton, Essex, April 5, 1827.

The son of a scientist, he has held during his career professorships at Edinburgh, Glasgow, and King's College Hospital, London. He was house-surgeon to the great Syme, whose daughter he married. His original work has included observations on the coagulation of the blood, on inflammation, on the fibre of the involuntary muscles. But his greatest triumph—the greatest triumph in surgery of the age - has been the introduction of the antiseptic treatment. The effect of this is so great that it seems impossible to realise that the reform has come about within living memory. The use of anæsthetics took surgery at a bound far in advance of the methods of the past. The surgeon had no longer to depend simply upon nerve and speed for the successful performance of an operation. His patient feeling no pain during the operation, he was able to do his work carefully at his leisure, and to observe all the signs necessary to the proper treatment of the case. But to counterbalance this boon there were the deadliest after-effects. The wounds became corrupt, and the healthiest patients died of blood-poisoning. People were afraid to enter hospitals, so terrible was the mortality rate after operations. New wards, new hospitals, were built, in the belief that the fault lay with the old buildings, but the deaths in the new buildings were as numerous as in the old. Lord Lister, seizing upon the discoveries of Pasteur as to the prevention of putrefaction by atmospheric organisms, saw that he must render the wound insusceptible to the influence of these deadly foes. His purpose was effected by the use of carbolic acid. First methods were necessarily crude, but these led step by step to the ultimate goal. The highest honours have been bestowed upon this great benefactor of the human race, and his fame is world-wide. He is the first man ever called to the House of Lords in recognition of his supreme eminence as a medical man.

Liszt, Franz

b. Raiding, Hungary, Oct. 22, 1811. d. Baireuth, Germany, July 31, 1886

The Paganini of the piano determined that he would attain to that degree of perfection after hearing the great violinist play. He was already master of the instrument, having played, when only nine years of age, at a great concert at which Beethoven was present. In recognition of his talent, six Hungarian nobles had defrayed the cost of his education. His career as a virtuoso began in his twenty-eighth year, when he won triumph upon triumph in the great cities of Europe. His earlier performances had won appreciation and wider knowledge for the work of Beethoven. He was now able to introduce the music of Wagner, Berlioz, and Chopin. Settling down for a time as director of the Court Theatre at Weimar, he produced Berlioz's "Benvenuto Cellini" and two of the operas of Wagner, to whom a daughter of his was married. In 1865 Liszt entered the Church, to be known thenceforward as the "Abbé Liszt." His compositions, which previously had been brilliant works for the pianoforte, now became mainly suited to the use of churches. Before his death he was ennobled and granted a handsome pension by his native country.

Livingstone, David

b. Blantyre, Lanarkshire, March 19, 1813. d. Ilala, Africa, May 1, 1873

The son of quite a poor man, he had to begin work as a piecer in a cotton factory when ten years of age. With his first wages he bought a Latin grammar, and by its aid mastered Virgil and Horace. His evenings were devoted to study, although he had to be in his place at the factory by six o'clock in the morning. While at work he used to fix his book on the spinning-jenny, so that he might glance at it in passing. At nineteen he was earning enough money to admit of his attending classes for the study of medicine, Greek, and divinity. He had already made up his mind to be a missionary. It was to China that his heart turned, and he would have gone there had not the opium war prevented it. He went to Africa instead, and there found his vocation as missionary and explorer. His first work was among the Bechuana, whom he befriended as doctor and missionary. During these years he married a daughter of his friend and leader, Dr. Moffatt. The failure, through Boer dislike, of his proposal to plant native missionaries in the Transvaal, set him upon his travels. Without attempting to tell the whole story of his stirring career, of his voyages to and from England, his receptions and honours, it is possible briefly to summarise his achievements. He discovered Lake Ngami in 1849; explored the Zambesi and Kuanza basins to Loanda, 1851-4; recrossed the continent from Loanda to Quilimane, discovering the vast Victoria Falls, in 1855; led a Government expedition up the Zambesi and Shire rivers, and discovered Lakes Shirwa and Nyassa, 1858-9; explored the Rovuma Valley in 1866, the Chambezi in 1867, and Lakes Tanganyika, Moero, and Bangweolo, 1867-9; was at Ujiji in 1869; navigated Tanganyika, and was relieved when in precarious plight by Stanley, at Ujiji in 1871; parted from Stanley at Unyanyembe in 1872, and returned to Lake Bangweolo. During these years he had had many trials, mental as well as physical. He had been grieved by the prevalence and extension of the slave trade carried on by the Portuguese, and had battled strenuously against it. He had suffered severely from privation and fever and dysentery. He succumbed at last at Ilala. His faithful native servants found him dead in the morning. He had passed away as he knelt at prayer. They reverently embalmed his body and carried it to the coast, to be brought home and laid in Westminster Abbey. Livingstone was a great Christian hero, a bold and skilful explorer, whose services to humanity and to geography were of the highest order.

Livy, Titus Livius
b. Patavium, Italy, 59 B.C. d. Patavium, 17 A.D.
Of patrician birth, he became a favourite at the Court of Augustus, but never hid the fact that his sympathies were with a republican form of Government. His fearlessness and impartiality are reflected in his monumental work, his history of Rome. To this great undertaking he devoted forty years of his life. It was in 142 books, of which thirty-five are extant, and traced the story of Rome from her beginnings down to the first decade after the birth of Christ. This, the chief of his life's work, placed him in the forefront of prose writers of the Augustan age.

Locke, John
b. Wrington, Somerset, Aug. 29, 1632. d. Oates, Essex, Oct. 28, 1704.
His father, a country lawyer, had served under the Parliament in the wars of the Commonwealth. Locke's sympathies inclined the same way, which fact, coupled with his ill-health, made it desirable for him to reside abroad--mainly in Holland--until after the Revolution of 1688. His immortal essay on the "Human Understanding" was published in 1690, and remains to this day one of the most notable contributions to the philosophy of the human mind. His writings on toleration and government have had a great influence in diffusing free and generous sentiments through European and American systems of government. He at one time intended to be a doctor, and did practise a little. His skilful diagnosis of the complaint from which Lord Shaftesbury, his friend and patron, suffered was the beginning of their friendship. Newton also was among his friends, and they had long corresponded when mighty things were being accomplished by them in the world of abstract science.

Lodge, Sir Oliver Joseph
b. near Stoke, Staffs, June 12, 1851.
While acting first as Professor of Physics at Liverpool University, and as Principal of Birmingham University, he has found time to undertake original experiments of the highest importance. He is one of the pioneers of wireless telegraphy, and has in hand an invention for dispelling fog. Actively interested in religious and social questions, he has made striking contributions to the literature of both subjects. Psychical research also engages his sympathies and keen attention.

Longfellow, Henry Wadsworth
b. Portland, Maine Feb. 27, 1807. d. Cambridge, Mass., March 24, 1882
At nineteen he was sent by the trustees of his college to Europe to study languages, and passed two profitable years on the Continent. This qualified him for the chair of Modern Languages and Literature at Harvard, which he occupied for seventeen years. He wrote his first poem as a boy, and to the last the muse seldom deserted him. He is the one American poet whose poems are universally known. His poems are songs of gladness and sweetness and purity. He is the poet of life, as Poe is the poet of death. Longfellow was twice married, and several times visited Europe.

Longman, Thomas
b. Bristol, 1699. d. London, June 18, 1755.
The son of a soap-boiler, he was apprenticed to a London bookseller, and founded the great publishing house of Longman & Co., by whom, during the last century and a half, some of the finest works in the English language have been issued to the world. He began business for himself by buying out the first publisher of "Robinson Crusoe," in premises whose site is still occupied by the firm.

Low, Sampson
b. London, Nov. 1797. d. London. April 16, 1886.
The son of a printer and bookseller, he established the famous publishing house of Sampson Low & Co. His own house contributed works of great value to literary students—works of reference, indexes, and so forth. Many excellent philanthropies were assisted by his judicious and generous efforts.

Lowell, James Russell
b. Cambridge, Mass., Feb. 22, 1819. d. Cambridge, Mass., Aug. 12, 1891.
Essayist, poet, scholar, and diplomatist, he filled the chair at Harvard which Longfellow had formerly occupied. Although he was a successful Ambassador to Spain and England, he never better served the cause of his country and humanity than in his poems. "The Biglow Papers," were called forth by the efforts of the North to free the slaves. Of the latter he was an unswerving and warm-hearted friend.

Loyola, Ignatius de
b. Loyola, Spain, 1491 d. Rome, July 31, 1556.
Iñigo Lopez de Recalde was the real name of the founder of the Jesuits. In his youth he was the very prototype of Don Quixote; but a serious injury, which left him crippled for life, caused him to turn his attention to loftier ideals than those of chivalry. The Church of Rome was at that time reduced to the depths of degradation by corruption and the luxury of its dignitaries. After making a pilgrimage to the Holy Land, he established the Society of Jesus, whose members were to be missionaries, to go to the uttermost parts of the earth at the bidding of the Pope, to convert the heathen to Christianity. The future of this society was destined to be very different from that which he had planned; but the name of Loyola stands out in the Catholic Church as does that of Luther in the Protestant.

Lucian
b. Samosata, Syria, about 120 A.D. d. Egypt, about 200
His father was a poor stonemason, and intended him to follow the same trade with himself; but Lucian managed to get an education, and to maintain himself as an orator and advocate. Thereafter he settled at Athens, where his literary works were composed. Of these many remain. They are brilliant satires, parodies, and mock narratives of travel, upon which tales such as "Gulliver's Travels" are modelled. He is alleged to have been torn to pieces by dogs, but that is probably an invention of the early Christians, the more likely version being that he died in peace in Egypt, whither he had gone to enjoy a lucrative office.

Lucretius, Titus Carus
b. Rome, about 99 B.C. d. Rome, about 55 B.C.
Little is known of the personal history of this celebrated Roman poet and philosopher. He was the intellectual link between Ennius and Virgil. He lived the life of a recluse. One version as to his death has it that he committed suicide in a fit of insanity; the other, with which Tennyson's poem has familiarised us, that he was poisoned by a love-philtre administered by his wife Lucilia.

Luther, Martin
b. Eisleben, Saxony, Nov 10, 1483. d. Eisleben, Feb. 18, 1546.
His father was a working man, who gave him a university education, and greatly regretted his entering a monastery. It was here, however, that the reformer was enabled closely to apply himself to the study of the Scriptures, and to develop his powers as an orator. His first sign of disagreement with the Church of Rome was brought about by the shameless sale of indulgences. Luther nailed on to the church door of Wittenberg a denunciation of this traffic, and of the Pope's title to forgive sins. The Pope summoned him to Rome. Luther refused to obey the summons. His works were ordered to be burnt, and the Pope excommunicated him. Luther retaliated by burning the Papal Bull containing the sentence upon him. The reformer published his famous "Address to the Christian Nobles of Germany," following it up with his treatise on the "Babylonish Captivity of the Church." Matters had now assumed so serious an aspect that Charles V. summoned him to attend the Diet of Worms, where, in

spite of a powerful defence of his doctrines, he was proscribed. After this he was for some time in hiding, and turned the period to account by translating the New Testament into German. The Old Testament was afterwards similarly treated, and the hymns were written and published from time to time. His writings had immense influence. They created the modern German language. The effect of his stand against the Pope was far-reaching. Europe started like a giant from sleep at the blasts of his trumpet. Dauntless, inspired, invincible, he was rough and violent in his battles, but it was against unprecedented odds that he was matched. When he thought he saw the devil, he threw his ink-horn at the apparition. That was characteristic of his methods. He stands out a great, magnificent figure, initiator of an impulse which became a mighty struggle still in progress. After he had finally broken from Rome, he renounced his monastic habit and married.

Lyell, Sir Charles
b. Kinnordy, Forfarshire, Nov. 14, 1797. d. London, Feb 22, 1875.

A good classical scholar, a man of many friends, Lyell must have distinguished himself in whatever pursuit he had followed. Geology was his absorbing passion. His "Principles of Geology" ranks next to the "Origin of Species" as among the books which influenced the scientific thought of the century. Darwin rated his work very highly, saying that no other geologist had ever done as much for science as Lyell. He was very near-sighted, a fact which may have accounted for his being not the keenest of field observers.

Lytton, Edward George Earle Bulwer, Lord
b. London, May 25, 1803, d. Torquay, Jan 18, 1873

His father was a general; his mother, Elizabeth Barbara Lytton, heiress of Knebworth. After a university education he married, against his mother's wishes, a beautiful woman, with whom his union proved very unhappy. Husband and wife parted after nine years. In that time, to maintain his house, he had produced novels, plays, essays, reviews. He continued an indefatigable workman to the end of his days. After he had inherited Knebworth, he entered Parliament, and became a successful Colonial Secretary.

Macadam, John Loudon
b. Ayr, Sept. 21, 1756. d. London, Nov. 26, 1836.

The man who, in modern England, first gave us good roads—the "macadam" roads, called after himself—was taken by his parents to America, but came back to England, and undertook victualling appointments for the Navy. His road-making experiments were begun at Bristol, and afterwards extended to London. His labour brought him to poverty, and he was voted £10,000 by Government.

Macaulay, Thomas Babington
b. Rothley Temple, Leicestershire, Oct. 25, 1800. d. London, Dec. 28, 1859.

With the story of his childhood every schoolboy is familiar. He was another Victor Hugo in his amazing precocity. His career at Cambridge did not realise all the expectations which his friends had formed; but, nevertheless, he got his coveted fellowship, and faced the world one of the completest scholars ever known. Not only was his scholarship wide and deep; his memory was abnormal. What he read he never forgot—prose or poetry. This was of immense help to him in his writings, essays, criticisms, and history. His early career was threatened by the failing fortunes of his father, and it stands to his credit that three years after he had entered public life he contemplated retirement rather than go with a weak-kneed Government which paltered with principles dear to him. Minor offices paved the way to his going to India as a member of the Supreme Indian Council, at Calcutta. The result of his work became, eventually the admirable Indian penal code. What he gained in knowledge of Indian life is reflected in his superb essays on Clive and Warren Hastings. Upon his return to England, he twice represented Edinburgh in Parliament, but literature absorbed his interest. His history was the ambition of his life. He had brought it down to the reign of William III. when death stayed his hand. That, like his essays, is a masterpiece of writing—as a picture of historical pageants, as portraiture of men; but it does not bear the analysis of the impartial student of history. He was a partisan, and let his partisanship influence his judgment on affairs of which he had undertaken to narrate the true story. Still, there is in the history that which not even Gibbon could have equalled, and, for all his honest prejudices appearing again and again, it lives as one of the glories of English literature. Macaulay was famous as a conversationalist. He was a hard-hitting enemy in public, but a true, loyal, and generous friend, and one of the best-loved men of his age.

Machiavelli, Nicoli di Bernardo dei
b. Florence, May 3, 1469 d. Florence, June, 22, 1527.

Descended from a noble but impoverished family, he lived in an age when troubles were heavy upon Florence. He saw the Medici expelled, the Republic instituted and dissolved, and the Medici reinstated. In the meantime he had fulfilled many diplomatic missions, and taken a prominent part in public life. The restoration of the Medici led to his being put to the torture as a conspirator against the ruling family. Thereafter he retired, to devote himself, for the greater part of his remaining years, to literature. He presented a notable report to Leo X. on the reforms for Florence, and afterwards acted as ambassador. His name has been made the synonym for deceit and villainy. His aims and purpose were misunderstood by early commentators. Modern critics hold that Machiavelli was a man whose public conduct was upright and honourable, whose views of morality, where they differed from those of the persons around him, differed only for the better. His fault was that, having adopted some of the maxims then generally received, he arranged them more luminously, and expressed them more forcibly, than any other writer.

Macmillan, Daniel
b. Arran, Sept. 13, 1813. d. Cambridge, June 27, 1857

The son of a small farmer, he came to London as a raw lad, worked for some years in the employ of a Cambridge bookseller, then with a man of the same trade in Fleet Street, and finally, with his brother Alexander, founded what has since developed into the famous publishing house of Macmillan & Co.

Maeterlinck, Maurice
b. Ghent, 1864.

Educated in a Jesuit college, he forsook the law for literature. Falling early under the influence of Villiers de l'Ile Adam, in Paris, he gave to the world a succession of powerful dramas which have made him world famous. Of a different type, and happier, is his "Life of the Bee," which, whatever be the ultimate verdict upon his other works, seems to assure him lasting fame.

Magellan, Ferdinand
b. Sabaroso, Portugal, about 1480. d. Philippine Isles, April 27, 1521.

Brought up at the Portuguese Court, he served for some years in the East Indies, after which, feeling himself slighted, he took service with Spain. He sailed upon an expedition from which he was fated not to return. On the way, he proved that America is not a great continent stretching away to the South Pole. He made his way, by the straits which bear his name, to the great ocean which he named the Pacific. Reaching the Philippine Islands, he was slain by natives. One of his ships continued on her way, and sailed round the globe, for the first time in the history of the world. The feat was not equalled until Drake was successful more than fifty years later.

Mahomet
b. Mecca, Arabia, 570 A.D. d. Medina, Arabia, June 8, 632 A.D.

There are half a dozen renderings of the name Mahomet, which means "praised," or "the praised one." His father was poor, but of exalted lineage, one of the dominant tribe of Mecca. The Prophet was early left an orphan, and was educated by relatives. He became a soldier, and after that a shepherd. His travels brought him in contact with Jews and Christians, in scenes where idolatry was generally practised. Married at twenty-five, he was fortunate to have for helpmeet a rich woman, who loved and revered him. He would often flee the society of men, and seek the solitude of a cave beyond their reach. Here he pondered over what he had learned of Jew and Christian and from Arabian fable. He was seized with fits of alternating exaltation and despair. At last he became convinced that he had been sent into the world as the prophet of the one true God. His wife believed in his mission, and a few other converts were made. It took three years to get a congregation of forty believers. When once news of the new faith was noised abroad, persecution sharp and protracted followed. He had to flee from Mecca to Medina. Hitherto he had been simply a spiritual teacher; but now he gathered warriors about him, and conflicts many and bloody resulted before he subjugated his enemies. Slowly the faith which he preached made its way. Towards the close of his life progress was rapid, and he was able to add a temporal character to his rule. Mecca remained a holy city, but idolatry was swept away. His teachings were embodied in the Koran, the holy book of the Mohammedans. He pretended and, possibly, partly believed—that he received the laws which he interpreted direct from the angel Gabriel. Those laws, however, are largely drawn from the Old Testament and rabbinical sources. His followers to-day number one-sixth of the human race.

Manzoni, Alessandro
b. Milan, March 7, 1785. d. Milan, May 22, 1873

The founder of the modern Italian school of romance was the grandson of a great scholar, and was introduced early in life into the best literary circles in Italy. Beginning with sacred lyrics and a defence of the religious basis of morality, he startled the world first with a romantic comedy, followed by "Il Conte di Carmagnola," a novel which at once made him famous throughout Europe. The death of Napoleon called from his pen one of the noblest odes in modern literature. His life was singularly beautiful, though his griefs, through the loss by death of all those dear to him, were many and heavy.

Marconi, Guglielmo
b. Bologna, Italy, April 25, 1874

He studied first at Bologna, and then at Leghorn University, but began his experiments in wireless telegraphy at home. When only twenty-two years of age, he sent messages by his system across the Bristol Channel. His invention was adopted in 1900 by the Admiralty for a term of years; while the battleships of the Italian Navy, as well as those of this country, and many of the vessels of the ocean lines and mercantile marine, have since been fitted with his apparatus. Lloyds' stations at home and abroad and many of our lighthouses employ his system.

Marcus Aurelius
b. Rome, April 26, 121 A.D. d. Vienna, March 17, 180.

One of the noblest of the Roman emperors, his name originally was Marcus Annius Verus. He was adopted by Antonius Pius, Hadrian's successor, and eventually succeeded to the throne. He was more philosopher than warrior, and generously shared his dominions with his adoptive brother. His reign was marred by wars and pestilence. Though hating war, he became at the call of duty a great captain. Wherever he led his armies, a host of philosophers followed in his train. His immortal "Meditations," one of the most remarkable books in the Greek language, was really his diary. Its pages were never intended for any eye but his own. They represent the thoughts and feelings of a man of singularly pure heart and noble mind. He aimed at the highest standard of life of which he could conceive, and lived up to that standard.

Mariette, Auguste Edouard
b. Boulogne, Feb. 11, 1821 d. Cairo, Jan. 19, 1881.

His father was town clerk of Boulogne; but Mariette, after a liberal education, took a post at the grammar school, Stratford-on-Avon, after which he worked as a pattern-maker for a ribbon manufacturer at Coventry. Unable to settle, he returned home, and by chance was placed in possession of a mass of papers on matters relating to ancient Egypt. This changed the whole course of his life. He mastered the subject, and devoted the rest of his days to it. He excavated innumerable monuments and inscriptions in Egypt, working unweariedly in spite of ill-health. The world owes him gratitude for a vast store of knowledge of the ancient world. He lies buried in a sarcophagus in an Egyptian garden overlooking the great museum which is his noblest monument.

Marlborough, John Churchill, Duke of
b. Ashe, Devon, June 24, 1650. d. near Windsor, June 16, 1722.

The son of an impoverished Royalist, he was first page to the future James II., and a great favourite of Court ladies, one of whom—the Duchess of Cleveland—presented him with £5,000. Entering the Army, he saw a good deal of fighting; but promotion did not come his way until he married Sarah Jennings, who was to become in all but name Queen of England. He was now elevated to the peerage, but went over to William of Orange when the tide turned. His military exploits in Ireland and against the French did not establish his loyalty to the new dynasty, for he was imprisoned for complicity in Jacobite intrigues. Quickly restored to favour, he was promoted to the command of all the British forces, and in that capacity successfully fought one half of Europe, while at the same time keeping the other half in fighting order. He was a great general brave and modest, fearless and determined, yet a merciful conqueror; but he was one of the most avaricious men that ever lived, and not among the most truthful. He has, however, to be judged by the standard of his time. Rewards were heaped upon him by his country. His wife, the famous Duchess of Marlborough, who long survived him, became for many years dictatress of the Court, and disposed of places and Government offices as she chose. Queen Anne finally revolted, and this singular woman lived for many years in complete retirement, possessor of enormous wealth.

Marlowe, Christopher
b. Canterbury, Feb. 1564. d. London, June 1, 1593.

A shoemaker's son, he managed to equip himself at Cambridge University. When he reached London, he found the stage encumbered with "a litter of rude, rhyming farces and tragedies." These his mighty talent swept away. Like many another genius, he led a wild, erratic life, which fact makes it the more striking that in the few years at his disposal he should have produced so much work of brilliant quality. He prepared the way for the tragedies of Shakespeare, on whose early work his influence is clearly traceable. Marlowe met his death in a street brawl at Deptford.

Marvell, Andrew
b. Winestead, Yorks, March 31, 1621. d. London, Aug. 18, 1678.

After graduating at Cambridge, and spending four years in travel on the Continent, he became, upon Milton's recommendation, tutor to Cromwell's ward. Subsequently he was appointed

Milton's assistant in the Latin secretaryship. He sat in Parliament, and undertook with success certain diplomatic missions. His claims to fame, however, rest upon his friendship with Milton, his brilliant satires, and his poems. He was practically the first to recognise and proclaim the magnificent genius of "Paradise Lost."

Mason, Sir Josiah
b. Kidderminster, Feb., 1795. d. near Birmingham, June 16, 1881.
Beginning life as a hawker, he was successively carpenter, blacksmith, house-painter, and carpet-weaver. He discovered a way to make split key-rings by machinery, and then set up in business as a penmaker. He made the pens which became famous as Perry's, the name of the London stationer who sold them. Mason engaged in other considerable enterprises, and retired with a great fortune, nearly the whole of which he devoted to philanthropies, whose benefits should long be enjoyed.

Maurice, John Frederick Denison
b. near Lowestoft, Aug. 29, 1805. d. London, April 1, 1872.
As a Dissenter, he quitted Cambridge without taking a degree; but under the influence of Coleridge he went to Oxford, and took orders. Becoming the leader of the Christian Socialist movement, he exercised great influence throughout the country. He was the founder of, and taught in, the Working Men's College and the Queen's College for Women. He held various livings and professorships.

Maximilian I.
b. March 22, 1459. d. Wels, Austria, Jan. 12, 1519.
The son of Frederick III., this great German Emperor was elected Emperor of the Holy Roman Empire, and greatly extended the area of his dominions. Wars occupied a considerable part of his reign, but his ideal was peace. In his day learning flourished, the administration of justice was improved, and he gave cordial encouragement to the pursuit of arts.

Maxwell, James Clerk.
b. Edinburgh, June 13, 1831. d. Cambridge, Nov. 5, 1879.
After a successful career at Cambridge University, he became first occupant of the Chair of Experimental Physics established there by the Duke of Devonshire. He held other professorships, and was one of the greatest and best-loved teachers of his age. Although he lived only forty-eight years, thirty-three of those years were precious to science. His first scientific paper was read before a learned society when he was only fifteen. The greatest work of his life, his "Electricity and Magnetism," was justly regarded as the "Principia" of the nineteenth century.

Mazzini, Giuseppe
b. Genoa, June 22, 1805. d. Pisa, Italy, March 10, 1872.
He was one of the national heroes called to act with spirit and determination in the hour of Italy's greatest depression and degradation. Well educated and a fiery enthusiast, he first associated himself with secret societies, but, abandoning these, set on foot the Young Italy movement, whose watchword was "God and the People." He was banished from Italy, from France, and from Switzerland; but returned to his native land, to be appointed, with Saffi and Armellini, one of a triumvirate with dictatorial powers. Overpowered by the troops of Napoleon III., he had again to flee. After that, though his life was still eventful, he no longer played a really important part in Italian history. He had already earned the gratitude of his countrymen in firing them with hope and courage to strive for the unity which they were enabled to gain.

Mencius
b. Tsow, China, 372 B.C. d. China, 289 B.C.
The lineal descendants of this Chinese philosopher are said still to live in his native province. His teachings are studied by every scholar in China. When forty years of age, after a diligent study of Confucius, he went forth on a twenty years' pilgrimage, seeking a prince who would give effect to his system of social and political order. His system recognised the innate good of man, and desired a form of government which should do the greatest good to the greatest number. His quest was unsuccessful, and he retired with his disciples, never again to emerge into active life.

Mendelssohn-Bartholdy Felix
b. Hamburg, Feb. 3, 1809. d. Leipzig, Nov. 4, 1847.
The name of this composer was built up in three stages. His grandfather, Moses Mendelssohn, the philosopher, was born Mendel; his father added the Bartholdy to the already lengthened name. Mendelssohn was a wonderful boy, and before he was twenty had earned lasting fame. Hamburg and Berlin did not adequately honour him; London did. He loved England all his days, and produced here some of his finest work. His "Elijah" was first given at the Birmingham Festival. A Scottish tour inspired the "Hebrides" overture and the Scotch Symphony. "St. Paul" was given at Birmingham after having been produced at Düsseldorf, where for three years he held an appointment. His years, all too few, were singularly productive. At sixteen he gave the world that almost unequalled example of early musical talent, the overture to the "Midsummer Night's Dream." His last great work was the "Elijah." Two other oratorios which he had begun were left unfinished. Mendelssohn was a fine instrumentalist, a talented painter, and a charming correspondent.

Meredith, George
b. Hampshire, Feb. 12, 1828.
His early education was received in Germany, where, taken as a child, he remained until he was fifteen. Returning to England, he vainly endeavoured to interest himself in the law. Literature was his natural avocation. It was as a poet that he first courted attention. Afterwards he entered journalism, edited an Eastern Counties' paper, and acted as special correspondent for a London daily during the Austro-Italian War. For some little time he edited a review while Mr. John Morley, its regular editor, was absent in America; and for years he was the valued literary adviser to a publishing house. His introduction proper to the world of letters came with the "Shaving of Shagpat," followed, three years later, by the triumphant appearance of "The Ordeal of Richard Feverel." But it was his "Diana of the Crossways" which announced to the greater world—that world beyond the discerning few—that a new power had arisen—a new man come to the head of contemporary novelists. The list of his publications—fiction and verse—is too long for enumeration. His work leaves him one of the giants of nineteenth-century literature. In his old age he considerably altered some of the best of his early work. His place in the hierarchy of literary immortals is assured; but he will be judged on the earlier and better versions, which in his declining days he damaged in the attempt to improve.

Michelangelo
b. Caprese, Italy, March 6, 1475. d. Rome, Feb. 18, 1564.
It used to be considered beneath the dignity of a nobleman to learn to read and write. The father of Michelangelo—whose full name was Michelangelo Buonarroti—looked with disfavour on his son's taste for drawing, deeming art unworthy of a gentleman. But the boy, who was destined to wear the four crowns of sculpture, architecture, painting, and poetry, was permitted to follow his natural bent, and in due course was apprenticed to a painter. Soon came the opportunity to develop his love for sculpture. Michelangelo's proficiency in this art led to his rival, Torregiano, smashing his nose with a mallet. By the time he

had reached his thirty-first year he was famous as sculptor and painter, and was summoned to Rome to undertake the vast tomb of the Pope, Julius II. He was destined never to finish it. For forty years, off and on, he returned to what he felt was the work of his life, but all was vexation. Conspiracy and other influences caused his energies to be diverted into different channels. One of these led to his producing that world-wonder, the fresco decoration of the Sistine Chapel, a stupendous work, done entirely by his own hand after ver four years' labour. After the death of Julius he returned to Florence, where he produced some of his most famous statues. Again he was torn from his work—this time to organise the fortifications of Florence, in the defence of which, against the Medici princes, he took a foremost part. Again he went to Rome, wnere he designed the cupola of St. Peter's. He laboured to the last at his gigantic tasks. There never was a greater genius, there never was a more indefatigable man; and it was his boast to the end that he was ever a student. "I am still learning," he said shortly before he died. Had he never painted a picture, he would have been immortal as a sculptor; had he never seen marble, his fame as a painter would have endured as long as history; had he neither painted nor carved, he would live as a poet. His influence on the whole realm of art has been little, if at all, inferior to that produced on the realm of thought by Homer and Dante.

Mill, John Stuart
b, London, May 20, 1806. d. Avignon, France, May 8, 1873.

The childhood of the "Saint of Rationalism," as Gladstone called him, has no parallel. His father made him an intellectual machine. At three he was studying the Greek alphabet; at eight, mastering the classics in the original; at twelve, besides studying Euclid and algebra, he was acting as instructor to the younger members of the family. When only thirty years of age, he was given charge, in the India House, of all the Company's relations with native states; and it eventually fell to him to prepare the case against the transfer of the government of India to the Crown. The transfer having been effected, he retired, amply compensated, and had time to turn his attention to philosophical studies. He debated and wrote and collected data, with a view to writing a history of the French Revolution. Finding that Carlyle was engaged upon a similar task, he generously handed over to him all his materials. It was to Mill that Carlyle lent the manuscript of his first volume of the "History." A careless maid burnt it, to the infinite distress of poor Mill and the nobly-borne agony of Carlyle. Mill made amends, when the book did appear, by writing a brilliant review of it, at once focussing public interest upon it. After some years of quiet work, Mill produced the works on logic, government, and political economy, upon which his fame is based. He sat for some years in Parliament; but the life, though patiently endured, was not to his liking, and he accepted his ultimate defeat with perfect composure. His contributions to logic and political economy have greatly advanced and popularised those subjects, and widely influenced modern political thought.

Millais, Sir John Everett
b. Southampton, June 8, 1829. d. London, Aug. 13, 1896.

He began his career as a student at the Royal Academy when only eleven, and at seventeen first exhibited a picture. With Hunt and Rossetti he formed the Pre-Raphaelite Brotherhood, which aimed at painting Nature as she presents herself rather than as the artist may choose to idealise her. He was excellent in portraiture, landscapes, and general paintings. Engravings and other reproductions have made his pictures famous all over the world. Millais, who married the lady who was first the wife of Ruskin, was made a baronet, and was one of the most popular men of his time.

Miller, Hugh
b. Cromarty, Oct. 10, 1802. d. near Edinburgh, Dec. 23, 1856.

One of Nature's gentlemen, he was a working stonemason, who distinguished himself first as a poet, then as a capable writer on religious and political subjects. His work in geology made him still more famous. Overwork ruined his health, and he committed suicide.

Millet, Jean Francois
b. Gruchy, France. Oct. 4, 1814. d. Barbizon, France, Jan. 20, 1875.

He was the farm labourer who became a great painter. The friendship of a discerning patron enabled him to acquire an artistic education, and a portrait sent to the Salon gained him fame. He fought in the Revolution of 1848, then settled down among the peasants and painted their life. His famous picture, "The Angelus"—of which thousands of copies are to be seen—sold, not many years after his death, for over £23,000.

Milton, John
b. London, Dec. 9, 1608. d. London, Nov. 8, 1674.

The Miltons were of Oxfordshire yeoman stock, but the poet's father, having become a Protestant, was compelled to settle in London and earn his livelihood as a scrivener. Milton went to Cambridge as a pensioner, and at twenty-four settled down for six quiet years under his father's roof, determined to consecrate his life to poetry. Here he produced "L'Allegro," "Il Penseroso," and "Lycidas." A tour of sixteen months on the Continent followed. He was recalled by a sense of duty. His country was on the eve of the Civil War, and he felt that he could not rest away while such serious conditions ruled. He acted as pamphleteer, and afterwards as Secretary for Foreign Tongues to the Commonwealth. When the Protectorate fell, Milton's prosperity was at an end and his safety endangered. Blindness attacked him at forty-four, and to the end of his days he had to depend upon the help of others. "Paradise Lost" was published in 1667, and, all told, brought the poet what in our money would amount to £70. He sold the copyright for £5. "Paradise Regained" and "Samson Agonistes" came out simultaneously four years before his death. He was thrice married, and, though he never actually knew the pinch of poverty, he was very poor in this world's goods for one so great. Fame had come to him before he died, but it was after his death that the world realised the mighty genius of the man who ranks with Homer, Dante, and Shakespeare as the greatest poet this world has seen. A blessing in disguise was the law of Laud, which forbade Milton's entering the Church as once he wished. He might have become a great prelate, but England would have lost the one great singer before whom only Shakespeare stands.

Moffatt, Robert
b. Ormiston, Scotland, Dec. 21, 1795. d. near Tonbridge, Kent, Aug. 9, 1883.

It was while working as an under-gardener that he studied for the missionary field. He devoted himself mainly to Bechuanaland, into the language of which country he translated the Bible. For half a century he laboured nobly in the wilds of the Dark Continent. Livingstone became his son-in-law.

Molière, Jean Baptiste
b. Paris, Jan. 15, 1622. d. Paris, Feb. 17, 1673.

Jean Baptiste Poquelin assumed the name by which he is known to all the world when he went upon the stage. This step in life he took after having studied under the Jesuits and read for the law. To the end of his days he devoted himself to writing plays and acting in them. He remains a colossal figure in French drama and poetry. To him the stage was always a lay pulpit; its aim not merely amusement, but reformation of manners by means of amusing spectacles. Ruskin shows how,

living in the blindest period of the civilised world's history, in the most luxurious city, and the most corrupted Court of the time, he yet manifests through all his writings an exquisite natural wisdom, a capacity for the most simple enjoyment, a high sense of nobleness, honour, and purity; and that, in all he says of art and science, he has an unerring instinct for what is useful and sincere, and uses his whole power to defend it.

Moltke, Helmuth Karl Bernhard, Count von
b. Parchim, Germany, Oct. 26, 1800. d. Berlin, April 24, 1891.
He began his military studies in Denmark, and entered the Danish Army. Transferring his services to the army of Prussia, he devoted his energies to raising that army to first-class rank. He was the chief strategist in the war against Denmark, in the Austro-Prussian War, and the Franco-Prussian War, and, with Bismarck, helped to make Germany a nation. His friends knew him as "the Silent." He was among the most modest of men, and added to supreme genius for war the capacity for unweariedly taking pains.

Montaigne, Michel Eyquem de
b. near Bordeaux, France, Feb. 28, 1533. d. near Bordeaux, Sept. 13, 1592.
The father of the modern essay was trained as a boy in Spartan ways. He was liberally educated, but treated as if he were one of the poor. This was in order that he might realise and sympathise with the lot of the humblest. Some years were passed at Court, and some devoted to extensive travels in Europe. He returned to France unwillingly, to accept the office of Mayor of Bordeaux, and discharged the duties of the office while inditing his immortal essays. These had enormous influence on the great men of his own and later ages. He examined all questions in the spirit of the sceptic; but upon his deathbed he devoutly received the last rites of his Church.

Montesquieu, Charles de Secondat
b. near Bordeaux, Jan. 18, 1689. d. Paris, Feb. 10, 1755.
Proceeding from college to the study of law, he first claimed attention by his clever criticism of the France of his day. This gained him election to the French Academy. After a spell of travel he settled down to the work of his life, of which the outstanding productions were his examination into the causes of the greatness and decline of the Romans, and his great work on the Spirit of Laws. To the latter task he devoted fourteen years. Although it was placed on the Index, it passed through twenty-two editions in the course of a couple of years, and had an enormous influence on the spirit of the age. Always a victim of weak sight, he became totally blind towards the close of his life.

Moore, Thomas
b. Dublin, May 28, 1779. d. near Devizes, Wilts, Feb. 25, 1852.
The son of an Irish grocer, he became one of the most popular poets and satirists of his time. Appointed to a sinecure post in Bermuda, he selected as his deputy a man who eventually misappropriated £6,000, which sum Moore repaid. His publishers, with unbounded faith, promised him £3,000 for his "Lallah Rookh," then unwritten; and though he offered to release them from their bargain, in consequence of the bad times, they held to, and profited by it. He made a handsome income, but was always poor, in spite of the providence of a model wife. He wrote the biography of Byron, and in turn had his own works edited by one of England's Prime Ministers —Lord John Russell.

More, Sir Thomas
b. London, Feb. 6, 1478. d. London, July 6, 1535.
Educated, as his father had been, to the law, he at one time seriously thought of turning monk. Statecraft later claimed his attention, and he became successively member of Parliament, Ambassador, Speaker of the House of Commons, and, in succession to Wolsey, Chancellor. He defended the Papacy against Martin Luther, and opposed the attack of Henry VIII. on the Church and his projected divorce of Catherine. Declining to swear adherence to the Act which vested the succession in the issue of Anne Boleyn, he was arrested and beheaded. Most famous of all his works is his "Utopia," in which he outlines a model community where all share the labours and rewards of an ideal life.

Morland, George
b. London, June 26, 1763. d. London, Oct. 27, 1804.
The history of genius has few sadder pages than that on which is inscribed the life story of this great artist. He worked, not for love of his art, but solely to get money with which to gratify sordid passions. He died miserably in a sponging-house. One of the finest of his works is in the National Gallery, and every year his pictures are increasingly esteemed.

Morley, John
b. Blackburn, Lancs, Dec. 24, 1838.
His father, like his elder brother, was a surgeon. On going to Oxford, he seems to have cherished the notion of entering the Church. In later years his views became pronouncedly agnostic. His earlier career in London was a struggle for footing in literature. He did not scorn the humblest work, but what he did he did well. Since then he has edited the "Fortnightly Review," the "Pall Mall Gazette," and two notable series of books. His own contributions to literature have included biographies of Burke, Voltaire, Rousseau, and Gladstone. The latter is a noble monument to a great statesman, nobly done by a scholar and loving friend. He has twice acted as Secretary for Ireland, and, upon Sir Henry Campbell-Bannerman becoming Prime Minister, was appointed Secretary for India.

Morris, William
b. Walthamstow, Essex, March 24, 1834. d. London, Oct. 3, 1896.
Painting was his first love, but poetry next claimed him for her own. He wrote many beautiful original poems and some striking translations, and set forth his Socialistic ideals in fine, nervous prose. He and a few kindred souls established a manufactory of artistic wallpapers, stained glass, pottery, and other articles of domestic use. The scheme was fanciful, but it had a great effect in reforming the taste of the country.

Morse, Samuel Finley Breese
b. Charlestown, Mass., April 27, 1791. d. New York, April 2, 1872.
The son of a clergyman, he graduated at Yale, and visited England to study portraiture under West. His efforts in art were unsuccessful in his native land, but his scheme for the electric telegraph well justified his existence. He conceived the idea in 1832, but not until fifteen years had elapsed could he induce the Government to establish a trial line between Baltimore and Washington. There was a dispute as to priority of discovery between the partisans of Morse and Wheatstone, but Morse deserved the honours which crowned his closing years.

Mozart, Wolfgang Amadeus Chrysostom
b. Salzburg, Austria, Jan. 27, 1756. d. Vienna, Dec. 5, 1791.
The world has never produced a greater musical genius than Mozart, and never treated another so badly. When he was a tiny child, all Europe was wildly enthusiastic over his marvellous abilities as instrumentalist and composer. By the time he had reached the age of twenty he had learned all that there was to be learned about music, and had to his credit many compositions which still live. But it was not easy to repeat the successes of his childhood. His genius, now fully matured, expressed itself in an unparalleled flood of musical glories. To every form of music he contributed superb works—opera, mass, symphony, concerto, sonata, song. All this time he was fighting for a bare livelihood for himself and his young wife. The greatest master of music in the history of the world had to look to lessons for his bread. It was

while his crowning work, "The Magic Flute," was being played that he received a mysterious order to compose a "Requiem." It was to be ready in a month. His breaking health sank under the manifold taxes to which he submitted himself. He declared that the work would be his own requiem, and it was. He died while still labouring at it. His death was one of the most pathetic in history. He was hurried into a pauper's grave, and to this day no man can say where his poor bones lie.

Murchison, Sir Roderick Impey
b. Tarradale, Ross-shire, Feb. 19, 1792. d. London, Oct. 22, 1871

Trained in a military academy, he entered the Army and fought in the Peninsular War. Exchanging into another regiment, in order to see more active service he was disappointed, but had the good fortune to meet the lady who became his wife and inspired his whole life's work. His geological discoveries, especially his establishment of the Silurian System, made him famous. It was he who, observing the resemblance between the Ural Mountains and the Australian chains, first predicted the discovery of gold in Australia.

Murdock, William
b. Auchinleck, Ayrshire, Aug. 25, 1754. d. Birmingham, Nov. 15, 1839

His father—who had been a gunner, but took up the trade of a millwright on returning to civil employment meant the future inventor to follow his own trade. Luckily, the youth found employment with Boulton & Watt at Birmingham, and was given responsible work in Cornwall, where the firm had important machinery plant. Here Murdock invented various improvements for the steam-engine. His most important discovery, however, was the distillation of illuminating gas from coal, wood, and peat. He lighted up his master's premises with the new illuminant in 1803, some years after he had begun experiments at his own house. His fame is overshadowed by that of the great men he served, but he was a man of striking original powers.

Murillo, Bartolomé Estéban
b. Seville, Spain, Jan. 1, 1618. d. Seville, April 3, 1682.

Humbly born, he owed his instruction in art to an uncle. When twenty-two, he had the good fortune to gain an introduction to Velasquez, who gave him an introduction at Court, which served to secure him ample patronage. His work was nearly all of an intensely devotional character, expressive of his own pious devotion. He married a wealthy wife, and enjoyed great prosperity. His death was brought about by a fall from a scaffolding while he was painting in a church in Cadiz. Some two hundred of his works are in England.

Murray, John
b. Edinburgh, 1745. d. November 6, 1793.

He joined the Royal Marines when seventeen years of age, but, disgusted with the monotony of the life, retired on half-pay at twenty-three, and turned bookseller. From the little business which he set up grew the world-famous publishing house of John Murray. The prosperity of the business was established by his son, John Murray II. (b. Nov. 27, 1778; d. June 27, 1843)—the "Anak of publishers," as Byron called him. He it was who started the "Quarterly Review," and paid Byron £20,000 for his works.

Musset, Alfred de
b. Paris, Dec. 11, 1810. d. Paris, May 1, 1857.

After a brilliant college career, he made a name for himself in literature at twenty, and followed with poems, comedies, tragedies, and short stories. Some of his poetry is perfect, but his work was unequal—a fact attributable largely to his irregular life.

Nansen, Fridtjof
b. near Christiania, Norway, Oct. 10, 1861.

He studied at the Universities of Christiania and Naples, and celebrated his majority by making his first voyage into the Arctic. A second followed seven years later, when he and five comrades crossed Greenland from east to west. This nerved him for his greater effort, the famous voyage in the Fram, when, in a three years' expedition—during which he permitted his ship to be frozen in, and to drift with the set of the ice—he succeeded in getting nearer to the North Pole than anyone else had previously done. Upon his native Norway being separated from Sweden, he was appointed first Ambassador of the new Power to England.

Napier, John
b. Edinburgh, 1550 d. Edinburgh, April 4, 1617

He was born when his father was less than seventeen years of age. Like his sire, he was keenly interested in scientific agriculture. In abstract science, however, lay his chief glory. His genius expressed itself in devising methods for lessening the labour of reckoning. His famous logarithms and the device known as "Napier's bones" were the concrete results of his genius by which he is best remembered. His discoveries were of vast importance to astronomy, navigation, surveying, and other pursuits involving complicated and elaborate calculations. His eldest son was ennobled.

Napoleon Bonaparte
b. Ajaccio, Corsica, Aug 15, 1769. d. St. Helena, May 5, 1821.

He was the second son of Carlo Bonaparte, who was of noble but impoverished family. His military studies began at Brienne, and were continued at Paris; but actual experience began in his seventeenth year, when he obtained a lieutenancy in an artillery regiment. The disturbed state of the nation, and the urgent need for officers with talent, made his promotion rapid. After commanding the Siege of Toulon against the Royalists, he was made a general, when only twenty-four. In another three years he was the most famous general in Europe. He married Josephine, a wealthy widow of much influence in Paris, and immediately set out for Italy, where he defeated the Austrians and Piedmontese, and entered Milan. Returning to France with the bays of many victories, he next entered upon a campaign against the eastern dominions of Britain. He conquered Egypt and Syria, but met with a reverse at Acre, where the defence was assisted by the English. Recalled to France by disturbing news of political disruption and of the loss of the newly-gained Italian territory, he was elected First Consul for ten years. Then, crossing the Alps, he swept down on Italy, and inflicted crushing blows upon the Austrians, winning for France the whole of Northern Italy. Various treaties gave the continent temporary peace, and Napoleon took advantage of it to reorganise France by means of the Code Napoleon, the establishment of the University, the National Bank, the Legion of Honour, and by the sweeping away of abuses which the Revolution had left. These were fruitful days, but war soon broke out again. He made elaborate preparations for the invasion of England, and even had a medal struck to commemorate the triumph which he was never to achieve. The Battle of Trafalgar effectually settled the question of invasion. Thereupon he turned his armies to Germany, where the tremendous victories of Ulm and Austerlitz were gained, to be followed by the overthrow of Prussia at Jena. He had now become hereditary Emperor, and attained the zenith of his power. One of his brothers was King of Naples, another was King of Holland, and a third was King of Westphalia. He himself was crowned King of Italy, and he now set his brother Joseph on the Spanish throne. The people rose in revolt. Wellington landed in Portugal, and the Peninsular War was begun. Many troubles now gathered about him; but after further battles he concluded peace with Austria, and married the daughter of her Royal house, having previously divorced

Josephine. Meanwhile, the Continental system—by which the commerce of England was to be boycotted—was in force, and it was the failure of the Tsar strictly to enforce it which led to war with that country. Napoleon marched a vast army to Moscow, but the city was fired, and he had to retreat in the depth of a Russian winter, harassed all the way by an indomitable foe. He lost four-fifths of the army with which he had set out, and, the allied armies of his enemies closing in upon Paris, he was compelled to abdicate. For a few months he lived as King of the Island of Elba, but returned secretly to France, regained the throne, and began the hundred days which ended in his final overthrow at Waterloo. He was taken prisoner to St. Helena, and died there, after five and a half wretched years, of cancer. Napoleon was the incarnate spirit of war, but he was great as an administrator. That he was cruel, and false, and treacherous, and filled with inordinate vanity, which cost the lives of millions of his fellow-creatures, every student of his history is aware. But such a man is not to be judged by ordinary standards. As Lord Rosebery has said, Napoleon came from Corsica a little pagan, viewing the world as his oyster. He was reared in the life of camps and in the terrors of revolution. He was raised to rule a nation which, in the horrors of a great convulsion, had formally renounced and practically abjured Christianity. He had to fight for his own hand against the whole world. It was breathless work, which gave little time for reflection. Before he died he saw all that he had built at such a cost of blood swept away. Had he died Emperor of France, no man could have followed him. His death must have created a gulf in which the whole apparatus of his government would have disappeared.

Nasmyth, James

b. Edinburgh, Aug. 19, 1808. d. London, May 7, 1890.

The Nasmyths were a talented family—the father a gifted portrait painter, a brother a landscape artist. James Nasmyth was the mechanical genius of the family. In 1839 he was informed that a steamship could not be built because there was no forge in existence big enough to forge its paddle-crank. In half an hour Nasmyth sketched his famous steam-hammer. The contrivance was built from that hurriedly-drawn sketch. He afterwards invented the steam pile-driver. Astronomy was one of his favourite studies, and he wrote a volume on the moon, which is still reprinted.

Nebuchadnezzar

began to reign, Babylon, 604 B.C. d. Babylon, 562 B.C.

As a warrior, architect, engineer, and ruler, Nebuchadnezzar was supreme in his age. He inherited from Nabopolassar, his father, a mere provincial city in Babylon. He made the city the wonder of all the ages; his dominions he so enlarged that they extended from Persia to Egypt, from Cicilia to the Persian Gulf. He besieged Jerusalem, and twice carried away its king, and swept all but the very outcast of the people into captivity. The rebellion of the Jews he punished with atrocious cruelty. Zedekiah—whom he had placed on the throne, but who had risen against him—he condemned to gaze on the slaughter of his own children. Then he put out his eyes, and led him in chains to Babylon. When Daniel interpreted his dreams he worshipped him, and bade all his people worship no god but the God of Daniel. For seven years his mind was clouded; but, recovering, he seems to have forsaken idolatry. His empire decayed after he died as rapidly as he had built it.

Nelson, Horatio, Viscount

b. Burnham Thorpe, Norfolk, Sept. 29, 1758. d. Trafalgar, Oct. 21, 1805.

A son of the rectory, he was a weakly boy, who never seemed likely to make a sailor; but experiences in the West Indies, and an expedition to the Arctic Regions, proved his metal. He was a post-captain at twenty-one, serving in the American War. War with France having been declared, he served under Hood and Hotham, and greatly distinguished himself at the battle off Cape St. Vincent, where for an hour his ship withstood the whole Spanish van and captured two vessels. Promoted to the rank of rear-admiral, he was sent to intercept Napoleon's expedition to Egypt. This he failed to do, but he came up with the French fleet in Aboukir Bay. The French were anchored in superior numbers, and Nelson planned a daring and original stroke. The wind was blowing against the French fleet, and he sailed down and took the enemy's ships one at a time. He captured or sunk all save four, which escaped, to be taken by him not long afterwards. Nelson went to Naples a hero. He had married some years before, but now he met Lady Hamilton at the Court of Naples, and they entered into that liaison which stains his name. He remained at Naples in defiance of orders, and when he reached England there was a stormy interview with his wife, after which they parted, never to meet again. He was censured for his disobedience at Naples, but there was too much fighting for him to remain idle. He directed the attack on Copenhagen and the Danish fleet, where he won new honours in a fierce and bloody battle. The after events in his life were but preliminaries to the Battle of Trafalgar. The French and Spanish fleets were allied; unless these were crushed, Napoleon's army would surely invade England. There were many delays and wearisome searchings by Nelson for the missing fleet. At last it was brought to battle off Cape Trafalgar. Nelson signalled to his fleet, "England expects that every man will do his duty." He had twenty-seven ships, the French and Spaniards thirty-three. The enemy's fleet was annihilated. Nelson himself fell, shot by a Frenchman in the tops of the Redoutable; but he lived long enough to know that his victory was complete and his country saved. He was the greatest naval warrior the world has known. He had all the genius and all the patience and the bravery essential to his work. In private he was a simple, unaffected man. In one battle he had an eye destroyed; in another he lost an arm; but he was always wholly a hero in battle. The one blot upon his fame is his relations with Lady Hamilton—a beautiful adventuress, who had become the wife of Sir William Hamilton. For her he sacrificed his personal honour and reputation as a moral man.

Newcomen, Thomas

b. Dartmouth, Feb. 1663. d. London (?), 1729.

He was one of the obscure, industrious geniuses to whom we owe the application of steam as a motive power. He was either an ironmonger or a blacksmith. Possessed of an original and inquiring mind, he corresponded with Robert Hooke as to the investigations of Papin and the Marquis of Worcester upon the applicability of steam-power for the purpose of driving machinery. He found a kindred spirit in Savery, a mine manager of Cornwall, and a sympathetic friend in Cawley, a glazier. The former was another born inventor; Cawley seems to have advanced the capital which Newcomen first needed for his experiments. The outcome was a patent for the "atmospheric steam-engine." Its purpose was to pump water from mines. This was the first piece of mechanism in which steam was used with practical success. Hero, of Alexandria, born two thousand years before, had discovered the power of steam, and applied it in the form of what was practically a primitive steam-turbine. For two thousand years the secret lay hidden, if it can be said ever to have been mastered. Possibly Newcomen never heard of Hero. He, at any rate, was the next man after the Alexandrian genius successfully to carry out experiments with steam. But Newcomen turned his experiments to practical account, and all our triumphs with steam date from his successful efforts.

Newman, John Henry
b. London, February 21, 1801. d. Birmingham, August 11, 1890.

The son of a banker, whose affairs became involved before the future cardinal had completed his Oxford course, he gained an Oriel Fellowship and took Orders. He threw himself with eagerness into the "Tractarian Movement" at Oxford, which landed him, as it had landed others, in the Roman Catholic Church. In his new faith he worked humbly and with zeal, and became famous for his sermons and lectures and writings. He had a singularly charming literary style, and was a poet of high order. His "Lead, Kindly Light" is the most popular of all hymns; his "Dream of Gerontius" is a work of striking beauty. He was created a cardinal in 1879, thirty-four years after his secession from the Anglican Church. His brother, Francis William Newman, was an educationist of renown, and did not follow John Henry to Rome.

Newton, Sir Isaac
b. Woolsthorpe, Lincs, December 25, 1642. d. London, March 20, 1727.

His father was a small freehold farmer. He was only twenty-one when he took his B.A. at Cambridge, and recorded his discovery of fluxions. A year later the great law of universal gravitation dawned upon him, suggested to his mind by the fall of an apple. His efforts to explain the lunar and planetary motions were fruitless, owing to the absence of reliable data as to the size of the earth, and he had to put aside his work, and turn to the investigation into the nature of light and the construction of telescopes. His discoveries as to the latter led to the construction of the first reflecting telescope, which later workers were to bring to perfection. Picard produced his estimate of the size of the earth in 1670, and Newton was able to resume, at the point where he had desisted, his speculations on the law of gravitation. Fourteen years elapsed before his completed theory was given to the world. Newton sat in Parliament, became Master of the Mint, and reformed the coinage; recommended public encouragement for an invention to determine longitude, and was for twenty-four years President of the Royal Society. He has been called the priest of Nature. No one before him had ever so clearly unfolded the laws by which the material world is regulated. He was one of the humblest of men, and spoke of himself as a child in knowledge.

Nightingale, Florence
b. Florence, May 15, 1820.

Although born in Florence, she is of English parentage. When quite a young woman, she made a tour of European hospitals, and on the outbreak of the Crimean War volunteered to organise a nursing department at Scutari. The terrible condition of the wounded was vastly improved under her skilful and sympathetic direction, and her work was the beginning of complete reforms in Army hospital methods. A public testimonial took the form of a £50,000 gift to her. This sum she devoted to the formation of a properly-equipped training institution for nurses.

Otho I. or Otto the Great
b. 912. d. Memleben, Germany, May 7, 973.

Succeeding his father, Henry I., as King of the Germans, he extended his dominions in various directions, suppressed rebellious nobles, restored the institutions of Charlemagne, and implanted Christianity in Scandinavian and Slavonic lands.

Owen, Sir Richard
b. Lancaster, July 20, 1804. d. London, December 18, 1892.

After study in Edinburgh and at a London hospital, he determined to enter the Navy. While hoping for an opening, he was offered the post of assistant to the curator of the museum of the Royal College of Surgeons. Here was housed the great collection got together by John Hunter, and it became Owen's task to classify and catalogue it. So, quite by chance, he was led to devote himself to science, and to make a lasting reputation as one of the foremost of British comparative anatomists and palæontologists. His work, slow to be recognised in official circles by his own countrymen, was honoured by every scientific academy in Europe.

Owen, Robert
b. Newtown, Wales, May 14, 1771. d. Newtown, November 17, 1858.

The founder of Socialism in Britain was the son of poor parents, and from the position of shop-boy rose to that of factory manager, and then cotton millowner. He put his Socialism to practical test by experimental plans in Scotland, America, Ireland, and England. The scheme, though it attracted widespread attention, was not a success, and brought him to comparative poverty. Nevertheless, he was instrumental in bringing about the first factory legislation. He was the pioneer of the co-operative movement, and schools for infants had their origin in his experiments.

Paganini, Niccolo
b. Genoa, February 18, 1784. d. Nice, May 27, 1840.

The prince of violinists was the son of a street-porter, who scourged him to study while yet an infant. He was performing in public at nine, and at seventeen was a blasé man of the world—a gambler and spendthrift. Then he disappeared for four years from public life, emerging at the age of twenty-one, to win triumph upon triumph in all the capitals of Europe. Gaunt and repellent of appearance, playing the violin with demonic force and spirit, and with effects such as no other man had ever produced, he exercised upon his audiences an influence quite hypnotic. Serious people in polite society declared that he was animated by evil spirits, and that he was accompanied on the concert platform by a "familiar." He made a large fortune, but lost heavily over speculations.

Palestrina, Giovanni Pierluigi da
b. Palestrina, Italy, about 1524. d. Rome, February 2, 1594.

It was to Palestrina that the Council of Trent entrusted the reform of Church music. He was the first to combine the art with the science of music, to give beauty as well as technical correctness. His work marked a new epoch in music.

Paley, William
b. Peterborough, July 1743. d. Lincoln, May 25, 1805.

After a successful career at college, he held various benefices, but was remarkable more for his writings than his spoken sermons. His principal work was the well-known "Evidences of Christianity."

Palissy, Bernard
b. near Agen, France, about 1509. d. Paris, 1589.

Industrial inventor, philosopher, and scientist, Palissy was one of the heroes of his century. His long and undaunted struggles with poverty while trying to discover the secret of the enamel for china are of the classics of industral history. Imprisoned as a Huguenot, he was released to continue his public works, but was again thrown into the Bastille because of his religion, and died in that infamous prison.

Palladio, Andrea
b. Vicenza, Italy, November 30, 1518. d. Vicenza, August 19, 1580.

The author of the Palladian style of architecture was the creator of many noble works in Italy, and the founder of the modern school of Italian architecture. He wrote as well as he designed, and his great book on architecture was of inestimable assistance, among others, to Inigo Jones, the great English architect.

Papin, Denis
b. Blois, France, August 22, 1647. d. London, 1712.

Regarded by the French as the inventor of the steam-engine and steam navigation, he certainly was one of the pioneers in these directions. He

did apply steam for driving a piston, but he looked not to the expansive force of steam, but to atmospheric pressure for mechanical power. His idea was developed by Newcomen, Brindley, and Smeaton, and undoubtedly paved the way for work upon more correct lines. Papin did important work in association with Huygens and Boyle, and set convention at naught by fitting a paddle-wheel worked by hand into a vessel in which he essayed to cross the Channel. He died in poverty and obscurity.

Paracelsus

b. Switzerland, December 17, 1493. d. Salzburg, September 23, 1541.

Paracelsus was the self-conferred name of Theophrastus Bombastus von Hohenheim, son of a Swiss physician; he early studied alchemy and chemistry, and by practical experiments learned the properties of metals and minerals. He was a vain-glorious creature, but the courage with which he advocated his theories was of great importance in affording a new impetus to the development of pharmaceutical chemistry and in encouraging research and investigation. From his labours many new chemical compounds were discovered.

Park, Mungo

b. Selkirkshire, September 10, 1771. d. Africa, 1805.

At twenty years of age, after having studied medicine and surgery, he set sail for Sumatra in the East-Indiaman *Worcester*, on which he held the post of assistant-surgeon. This led to his employment by the African Association, in whose behalf he undertook to explore the course of the Niger. After many startling adventures he returned to civilisation, and, in an interesting volume, threw light on the interior of the Dark Continent. Thereafter he settled down to practise as a country surgeon in Scotland. The life, however, proved impossible to him, and he again undertook an expedition into the interior of Africa. Starting from Pisania, on the Gambia, he lost thirty-eight of his forty-five companions. The survivors were attacked by natives at Boussa, and perished with him.

Pascal, Blaise

b. Clermont-Ferrand, France, June 19, 1623. d. Paris, August 19, 1662.

His father, early persuaded of the talents of the boy, gave him an excellent education, but kept him from the study of mathematics, to which he particularly inclined. In spite of this deprivation Pascal became one of the greatest mathematicians of his age, and is said to have "reconstructed" geometry while still a boy. He wrote, before the completion of his sixteenth year, a treatise on "Conic Sections," which attracted the attention of Descartes; and before he was nineteen had invented a calculating machine to help his father in his work. His investigations in connection with the vacuum and hydraulics were of great importance. His literary productions were of two kinds—scientific and philosophic, moral and theological. His "Provincial Letters," a satire on the moral theology of the Jesuits, and "Thoughts" are for all time. They had an extraordinary effect in Europe at the time of their production, and are still treasured by every people into whose language they have been translated.

Pasteur, Louis

b. D^le, France, December 27, 1822. d. St. Cloud, France, Sep. 28, 1895.

He was the son of a tanner, and when homesick and melancholy would say, "If I could only smell the tannery again I should be well." None of the early manifestations of genius which often foreshadow coming greatness was apparent in his case. His health was poor, and his mental faculties slow to develop. But he had industry and application, and, by working steadfastly at problems which had puzzled all the chemists and physicists of his time, made a discovery which at once placed him in a position of honour among contemporary scientists. This was the outcome of his work on tartrate crystals and "left-handed" tartrates, and led him on to his great discoveries in fermentation and the action of atmospheric organisms. He swept aside the chemical speculations as to spontaneous generation, and showed that wine and milk turn sour, and meat becomes putrid, from the effects of these atmospheric organisms. Exclude those, he said, and food and drink remain pure and sweet. It was not without the most delicate and intricate experiments that his point was proved. Once established, it effected a complete revolution in chemical and biological science. The way was prepared for Lord Lister and antiseptic surgery, and for a thousand-and-one applications of the discovery to commerce and food supply. By this time the tanner's son had established himself at the head of his calling. Many and severe tests were imposed upon him, but, thanks to his powers of patient research and quick and exact observation, he succeeded in all. He had never seen a silkworm until the silk-producers besought his aid in the extermination of a pest which was ruining their industry; but he stamped out the plague. He cured chicken cholera, which had been destroying 10 per cent. of the poultry of his country; and he reduced the mortality in anthrax from 10 to 1 per cent. These discoveries represented in money hundreds of millions of pounds. Even more important to the human race were his investigations as to the cause and cure of hydrophobia, which resulted in his finding a way of rendering dogs immune from the evil, and of curing human beings suffering from it.

Paul, St.

b. Tarsus, Cilicia. d. Rome, 64, A.D.

The son of Jewish parents, "a Hebrew of the Hebrews," he was named Saul, and put to the trade of a tent-maker. Going to Jerusalem, he studied under Gamaliel, who held a foremost place among the theologians of the city. Gamaliel was a broad-minded, tolerant man, but Paul imbibed only of his knowledge, not of his spirit, so that he became a great master of the law and traditions and precedents, and thoroughly acquainted with the Scriptures and current methods of interpretation. The future Apostle became prominent as a persecutor of the Jews, and was present at the stoning of Stephen. Then came his miraculous conversion, and his subsequent teaching and exposition of Christianity. He made missionary tours in Syria, Cyprus, Asia Minor, Macedonia, and elsewhere; was imprisoned and tried, appealed against his sentence, and was sent to Rome. There he was acquitted, so that he was able to resume his journeys, but, returning to Rome, suffered martyrdom under the brutal Nero. Avowedly the servant of Christianity, he was really its leader. For two centuries after his death his name was little regarded, though his work lived and flourished and extended. His position and labours became more fully recognised in the century of Ambrose, Athanasius, and Augustin, but it was reserved for later Christians to raise him to his right place in the rôle of priests and martyrs.

Paxton, Sir Joseph

b. near Woburn, Beds, August 3, 1801. d. Sydenham, June 8, 1865.

One of the best examples of the self-made man, Paxton began life as an ordinary working gardener on the estate of the Duke of Devonshire, for whom he modelled the famous Chatsworth gardens and conservatories. He sent in for competition a rough design for a building for the Great Exhibition in Hyde Park, which gained the prize. He saw the building erected, and afterwards transferred to Sydenham, where it exists still as the world-famous Crystal Palace. Paxton's useful and admirable life was crowned by the publication of several valuable horticultural works. As an instance of his powers of observation, it may be

noted that the excellence of his design for the Crystal Palace was its lightness and its grace of design. He adapted the idea from an aquatic plant on the Chatsworth estate.

Peabody, George

b. S. Danvers, Mass., February 18, 1795. d. London, November 4, 1869.

Starting on the lowest rung, he worked in various small shops as assistant to grocers, drapers, and storekeepers, until he had saved capital enough to become partner in a dry goods store. This was when he had attained the age of thirty-four. Eight years later he opened in London as a merchant banker. By unimpeachable methods he amassed a great fortune, and during his lifetime gave away one and a half millions for exploration, for education, and for the building of industrial homes in London. The Peabody buildings have been established out of the funds given by him for the purpose.

Peary, Robert Edwin

b. Cresson Springs, Penn., U.S.A., May 6, 1856.

The most persistent of Arctic explorers, he joined the American Navy in 1881, and from time to time has sought leave of absence to make "a dash for the Pole." He had done a good deal of survey and mapping work in silent lands and lonely waters, before the world at large heard of him, and thus prepared himself for the greater work with which his name was to become identified. In the expedition from which he returned in 1906 he got to within 200 miles of the Pole on the Greenland side, so eclipsing all existing records. The Abruzzi expedition went thirty miles nearer than Nansen's; Peary's got thirty miles beyond the point at which the Abruzzi expedition was driven back.

Peel, Sir Robert

b. near Bury, Lancs, February 5, 1788. d. London, July 2, 1850.

Consecrated to politics from his youth up, Peel was bidden by his father to aim no lower than the Premiership. "Bob, you dog, if you're not Prime Minister, I'll disinherit you!" his father used jestingly to say. But he was sworn to service with the wrong party. At heart a Whig, he was destined to lead, to break up, to reconstruct, and once more shatter the Conservatives. At twenty-four he was Chief Secretary for Ireland, and so hostile to Catholic claims for freedom that he was nicknamed "Orange Peel." Yet it fell to him, as Home Secretary, and Leader of the House of Commons, to propose to the House a Bill for Roman Catholic Emancipation, his earlier antipathy to which, he confessed, had been his sole reason for refusing to act with Canning. The Bill cost him his seat and broke up his party, though not at once. He carried several useful measures, of which his reform of the police force was the most conspicuous. As Leader of the Opposition during the next ten years he was brilliantly successful, and restored his party to power. On taking office as Prime Minister in 1841, he was supported by a Conservative party pledged to Protection, and it fell to him to destroy the system which he had been placed in power to maintain. He resigned, in order to allow Lord John Russell to sweep away the Corn Laws; but as Russell could not form a Government Peel returned, and himself abolished the taxes on food. His party revolted and defeated him, and he declared that he had done for all time with parties. His death, the result of an accident while riding, prevented his saying from being falsified. Although force of circumstances made him forsake principles to which he was pledged, the honesty and integrity of Peel are not to be impugned. The problem of his position was a difficult one, and was the more so from the fact that he never had a confidant in public life to trace the development of changes in his opinions. His youngest son became Speaker of the House of Commons in 1884, and held that position until 1895, when he was created Viscount Peel.

Penn, William

b. London, October 14, 1644. d. Ruscombe, Berks, July 30, 1718.

His father, the redoubtable Sir William Penn, sent him to Oxford, where he came under the ban of the powers for Nonconformity. Penn travelled, and took military service, but was recalled to his earlier ideas by a chance meeting with a Quaker minister, under whose influence he developed into a bold speaker and writer, carrying the war for freedom of conscience from England into Germany. Twice his free expressions of opinion brought him to gaol; but his trial in 1670 marked an epoch in English public life, in that it established for all time the immunity of juries. In 1681 he obtained from the Crown, in lieu of his father's claim upon it, a grant of territory in America called, after the admiral, Pennsylvania. Here he settled a numerous body of his co-religionists with a famous charter. He planned the city of Philadelphia, and became governor as well as proprietor of the colony. After the accession of William III., Penn was wrongfully accused of treasonable adherence to the deposed James II. His troubles were not ended, in the New World or the Old. The Colonial Constitution had proved unworkable, and there was much discontent. The colony did eventually prosper, but Penn, returning to England, suffered financial embarrassment, and was actually an inmate for nine months of the debtors' prison—the Fleet. To the end his life was harassed by pecuniary and political troubles. Penn is one of the men whose characters and actions Macaulay has wrongly appraised. The influence which he had at Court was invariably exerted for the succour of his persecuted brethren.

Pericles

b. Athens, 5th century B.C. d. Athens, 429 B.C.

Born of distinguished parents, Pericles was for forty years the leading statesman in Athens. In his day she reached her highest point in splendour and power. He obliterated all trace of oligarchical institutions; he made Athens an empire state; he took tribute of maritime allies, and devoted part of the money to the adornment of Athens with those glories which made the memory of the city immortal. To him she owed the Parthenon, Erechtheum, the Propylæa, the Odeum, and numberless other noble buildings, as well as some of her finest classical sculptures. He died of fever, contracted when the war between Athens and Sparta was at its height. He was an able general and a famous orator, but did his beloved Athens irreparable injury by not foreseeing that personal government, nobly as it worked in his hands, must be ultimately ruinous to a nation.

Perkin, Sir William Henry

b. London, March 12, 1838.

Sent to the City of London School, the only institution of the character at the time where scientific subjects were taught, he became, at seventeen years of age, assistant to H. W. Hofman, the great chemist. When in his eighteenth year Perkin, at Hofman's instigation, was seeking to make artificial quinine, he obtained unexpected results. He had discovered the way to manufacture an aniline purple or mauve from coal-tar. The discovery was patented, and at eighteen years of age he was within sight of potential wealth inestimable. The process was worked by himself, his brother, and father, who soon made a vast fortune from it. From that laboratory experiment dates the gigantic industry in coal-tar products—dyes, scents, disinfectants, essences, and a thousand other things, which, developed mainly in German laboratories, have added hundreds of millions of pounds to the wealth of the world.

Peter the Great
b. Moscow, June 9, 1672. d. St. Petersburg, February 8, 1725.

At first he reigned jointly with his half-brother, the weak-minded Ivan, but at his death reigned alone. He Europeanised his army, and set about the creation of a navy and the provision of harbours, of which, at this time, Russia had but one—Archangel. He seized Azov, and then set forth to see what civilisation was doing for other peoples. He visited several countries, eventually reaching England. At Amsterdam, disguised as a labourer, he worked as a shipwright, and devoted his leisure to the study of science and philosophy. From England he carried back engineers artificers, surgeons, artillerymen, and artisans to the number of 500. At home he encouraged literature, developed trade with other countries, organised a national Church, and founded St. Petersburg. He was engaged in many wars and internal rebellions during his reign, but he extended his dominions, and made Russia a civilised nation. A genius in creative ability, he was a savage in his wrath, an Asiatic in his pleasures. Allowing for his limitations, he fully deserves his title "Great," for he was one of the most remarkable men of any age.

Peter the Hermit
b. Amiens, France, about 1050. d. Huy, Belgium, July 7, 1115

Though not a great man in the best sense of the term, Peter the Hermit was one of the most astonishing figures of his age. First a soldier in the service of the Counts of Boulogne, he abandoned wife and family and became a monk. Roused by stories of the sufferings of Christians in Palestine, he went throughout Europe preaching a crusade. Blessed by the Pope, Urban II., he traversed a great part of Europe, riding bareheaded and barefooted, carrying a cross. Everywhere his fiery eloquence caused him to be received as an inspired prophet. A great multitude followed him, clamouring to be led forthwith to the Holy Land. With Peter at their head, a mob of 40,000 enthusiasts set forth. They fought and slew and pillaged their way to Constantinople, and were practically exterminated by the Turks at Nicæa. The Crusade, led by Godfrey of Bouillon, was accompanied by Peter the Hermit, who, during the long siege of Antioch, was among those to lose heart and desert. He was carried back, to undergo a public reprimand. When at last Jerusalem was taken, the triumphant Crusaders fell at his feet and offered him thanks, as the original inspirer of their expedition. The life of Peter the Hermit is an amazing example of the power of one gifted enthusiast to inspire to lofty heroism practically the whole people of a continent.

Petrarch, Francesco de Parenzo
b. Arezzo, Italy, July 20, 1374. d. Arquà, Italy, July 18, 1374.

The same decree which banished Dante from Florence sent into exile the father of Petrarch, who settled at Arezzo, where the founder of the Classical Revival was born. From his earliest years Petrarch devoted himself to the study of literature, and in the days of his youth wrote the lovely lyrics which have maintained his fame undimmed for sixteen centuries. The death of his father left him without means, and he had to enter the Church. He never became a priest, but held various minor benefices, conferred by admirers of his genius. Of these there were many and powerful, and kings competed for the distinction of having him at their Courts. The "Laura" whom he immortalised he first met when he was twenty-three. She is supposed to have been the wife of Hugues de Sade, and to have been the mother of eleven children. Petrarch's passion for her was of the purest and loftiest order, as was that of Dante for his Beatrice. At thirty-five Petrarch was recognised as the first scholar and poet of his age, and was crowned laureate in Rome. His life for many years was passed at Courts and in the society of the most learned and cultured men in Europe. His literary output was prodigious, and —vain are our own judgments!—he deemed the work which he now did the work upon which his fame would rest. As a fact, it was forgotten or eclipsed in a later age, and is never read in our own. Petrarch lives for posterity in the exquisite poems of his youth.

Petrie, Sir William Matthew Flinders
b. Woolwich, June 3, 1853.

The grandson of Captain Flinders, the Australian explorer, he has made the buried past of Egypt the mission of his life. Tombs and temples have been made to tell the wonderful story of a civilisation and culture in the East, in comparison with which the ancient arts of Greece are modern. His discoveries have meant practically the re-writing of ancient history.

Petty, Sir William
b. Romsey, Hants, May 26, 1623. d. London, December 16, 1687.

He was the son of a small clothier, and, going to sea while a boy, was left, by sailors jealous of his attainments, with a broken leg upon the coast of France. Instead of striving to return home, he raised money by teaching English and navigation in France, and then entered himself at the Jesuit College at Caen, Normandy, where he received a good general education. Continuing his studies in Holland, he passed on to Paris, whither he was drawn by the fame of its scientists, and became associated with several notable men. Upon returning to England he was still very poor, but gained reputation by the invention of a copying machine and by sketching proposals for the formation of a scientific society. That society did eventually come into being on the lines which he had planned. It was the famous Royal Society, and he was one of its founders. With increasing reputation he was appointed a Fellow of Brasenose College, Professor of Anatomy and Music. Next he was appointed physician to the Army in Ireland, and surveyed the land forfeited to soldiers. He acquired considerable possessions, and founded important industries. His daughter married Thomas Fitzmaurice, Earl of Kerry, and from this marriage descend the Marquises of Lansdowne.

Phidias
b. Athens, about 490 B.C. d. Athens about 432 B.C.

The greatest sculptor of antiquity had the good fortune to live when Pericles was bedecking Athens with beauty, and to receive commissions to execute the chief statues and to supervise all the similar work of the capital. He constructed the Propylæa and the Parthenon, and adorned them with stupendous figures, acclaimed by antiquity as the most impressive and beautiful ever produced by man. The glorious Elgin marbles, fragmentary remains of the Parthenon frieze, remain as some evidence of his masterly work. The enemies of Pericles, afraid openly to attack him, assailed him through his nearest friends, of whom Phidias was one. They charged him with appropriating gold intended for his wonderful statue of Zeus. He was able to prove his innocence of this, so they charged him with impiety, he having introduced a portrait of himself into the statue of the goddess. He is supposed to have died while in prison on this second charge.

Pindar
b. near Thebes, Greece, about 522 B.C. d. Argos, Greece, 443 B.C.

The most famous and popular lyric poet of his day, he is the only Greek poet of whose work any considerable portions remain to us. Those preserved are the four books of odes celebrating the victories won in the Olympian, Pythian, Nemean, and Isthmian games. They present a striking picture of the importance which the athletic contests of the age occupied in the minds of the cultured Greeks. Pindar wrote also hymns to the

gods, pæans, lamentations for the dead, as well as odes to the victors in the games. Only the last survive entire. Pindar was a member of a talented family, members of which were renowned as masters of the flute.

Pitt, William

b. near Bromley, Kent, May 28, 1759. d. Putney, January 23, 1806.

The second son of the Earl of Chatham, who trained him from his earliest years to politics, the younger Pitt took naturally to statesmanship, and when he became Chancellor of the Exchequer at twenty-three, and Prime Minister at twenty-four, he entered upon his tremendous responsibilities with as much confidence as if he had been twice his age. For twenty years his power was unbroken, and he established for himself a position as one of the greatest statesmen in history. He enhanced the powers of the House of Commons as the representatives of the nation; he abolished sinecure offices, and stamped out corruption; he reformed the revenue methods of the country, and re-established its finances. For long he managed to keep peace with the Continent, but the French Revolution at last drove him to war. His greatest triumph was Nelson's Trafalgar victory. Pitt was now designated the "Saviour of Europe." His reply has become a classic: "Europe is not to be saved by any one man. England has saved herself by her exertions, and will, as I trust, save Europe by her exertions." A month later came news of Napoleon's wonderful victory at Austerlitz, and this proved Pitt's death-blow. He died less than two months later. Pitt was a great orator, a great financier—except when his personal interests were engaged—a born leader of men, but he had his weaknesses. He conferred titles with cynical indifference to the claims of the recipients; he permitted scandalous corruption in the deal by which the union of England and Ireland was effected; he abandoned Parliamentary reform and the abolition of the slave-trade when opposition came from Parliament, and cast aside Catholic emancipation when the King objected. In private life he was blameworthy for his hard drinking—a weakness of his era—and for the hopeless incompetence with which he permitted his affairs to drift into confusion. Otherwise, his character was singularly amiable and exemplary, and on his death-bed he found consolation in reflecting on "the innocence of his life."

Plato

b. Ægina, about 427 B.C. d. Athens, 347 B.C.

A disciple of Socrates, and the teacher of Aristotle, his teaching, with that of his master and pupil, has largely controlled the progress of speculative thought to the present day. In his youth he was a gymnast, a soldier, and a poet. He burned his poems upon coming under the influence of Socrates. After the death of the latter he travelled, and was seized and sold as a slave in Ægina, but was ransomed. Returning now to Athens, he started his Academic School. The academy was a grove. There, and in his own garden, he would walk and talk with his disciples, teaching them mainly by conversation, and embodying the results of his thinking in his written "Dialogues." He enjoyed a peaceful and prosperous old age, and died at a wedding feast. All the best of his philosophical writings have been preserved, together with many whose authorship is not clearly traceable to him. Plato is the greatest master of Greek prose style that ever lived, and is accounted as unapproached among mankind for the magnificent sweep of clear intellect, and the beauty and gorgeousness of poetic expression of his expositions.

Playfair, Lyon, Lord

b. Meerut, India, May 21, 1819. d. London, May 30, 1898.

He began his scientific career under the noted chemists, Graham and Liebig, and turned his knowledge to account in the practical application of science to commerce and the everyday affairs of life. He managed an important bleaching works, and was the one to suggest ways and means of developing a little stream of oil in Derbyshire which was to prove the parent of the paraffin and petroleum industries of the world. He was King Edward's master in practical chemistry; he served on many commissions dealing with the health and commodities of the nation; he performed inestimable service for the cause of education. For many years he sat in Parliament, and acted as Deputy Speaker. His last letter was to Mrs. Gladstone, sympathising with her upon the death of her husband, whose decease preceded his own by only nine days.

Plutarch

b. Chæronea, Greece, about 46 A.D. d. Greece, about 120 A.D.

The encyclopædist of antiquity was educated at Athens, but visited Rome, and lectured there on philosophy. The greater part of his days, however, were spent at Chæronea, his native place. There he wrote his discourses and his immortal "Lives." With the latter every student is familiar. They are biographies of warriors, statesmen, legislators, and heroes of ages preceding his own. They are precious documents, based on records which have long been lost.

Poe, Edgar Allan

b. Boston, Mass., January 19, 1809. d. Baltimore, October 7, 1849.

This gloomy genius was left an orphan when three years of age, but was adopted by a wealthy and kind-hearted man whose generosity he ill requited. Educated in London and at the University of Virginia, he got into disgrace at the latter through dissipation and gambling, and was removed to his patron's counting-house. He absconded and enlisted, was bought out, and sent to a military academy, from which he was dismissed for neglect of duty. Thrown on his own resources, he wrote poems and criticisms and stories for newspapers and magazines, one of which he edited. His most famous story, "The Gold Bug," was written to win a £20 competition; his greatest poem, "The Raven," was written for a New York evening paper. He gave way periodically to gross intemperance, and was frequently in direst poverty. His wife died when his affairs were in a hopeless condition, and he attempted suicide. Recovering, he was about to marry a second time, when he had another outburst, and was picked up in a public street, sodden with drink and dying. He was a genius of a peculiar order, with all the infirmities of genius, and few of its redeeming qualities.

Polo, Marco

b. Venice, 1254. d. Venice, 1324.

One of the earliest and greatest of travellers, Marco Polo was only a boy when he set out with his father and uncle to China. The elder Polos had already wandered thither, had been handsomely received by Kublai Khan, the Emperor, and by him commissioned to lead a hundred learned men from Europe to the Celestial Empire. When they set out two friars accompanied them, but soon turned back, and the three Polos went on alone, by Sivus, Mosul, Bagdad, and Ormuz, through Khorasan, up the Oxus to the Pamir plateau, through Kashgar, Yarkand, along Lake Lob, over the Great Gobi Desert, and so to Shangtu, near the modern Peking, where Kublai Khan was staying. For seventeen years they were honoured guests at the Imperial Court. Marco was made an ambassador, and visited Cochin-China, India, and elsewhere. Finally, the three returned, wealthy, to their native land, coming back by way of Sumatra, the Straits of Malacca, Ceylon, and Ormuz. During a battle between the Venetians and Genoese, Marco was taken prisoner and cast into gaol. His misfortune

was a blessing to posterity, for he recounted his adventures to a fellow prisoner, who gave them to the world in the form of a book. That book did much to stimulate the love of travel, and was of great assistance to Columbus and other seekers after a sea-way to India.

Pope, Alexander

b. London, May 21, 1688. d. Twickenham, May 30, 1744.

His father, a linendraper, having become a convert to Roman Catholicism, Pope had no regular training in the public schools, but laboured with prodigious zeal privately to equip himself. His intense application to study while still a child ruined his health, and his sickly constitution undoubtedly gave that jaundiced bias to his mind by which he was throughout life affected. At twelve he had already begun to write poetry, and at fourteen produced his "Ode on Solitude," a surprising work for one so young. While he was still in his 'teens he was introduced by Wycherley into the society of the literary lions of the age—Addison, Steele, Swift, and Arbuthnot. "The Rape of the Lock," one of his finest productions, was published in his twenty-fourth year, and "Windsor Forest" in the year following. His translation of Homer began when he was twenty-four. The "Iliad" occupied him seven years, and brought him fame and fortune. The "Odyssey" occupied a further five years, and was not so successful, owing to his having entrusted parts of the work to hands less skilled than his own. "The Dunciad" was written while the "Odyssey" was in progress, but it was not published until 1728, so that between its completion and issue Pope might have time deliberately to sting into fury the victims of his lampoon, then represent their anger as having induced him to write it. This was characteristic of Pope, who was always planning and plotting to deceive posterity into a belief in and admiration for a spontaneity which he did not possess. The "Essay on Man," produced when he was forty-five, like two of his earlier works, abounds in lines and couplets which have passed into the habitual conversation of our lives. Pope was one of the most extraordinary geniuses produced by England. Soured by bodily infirmity, by perpetual animosities, and by ungratified vanity, he could stoop to the meanest, most stupid deceits, yet he was tender-hearted and loyal to the weak and suffering. He had inspiration, yet never passed a line or phrase until it had been refined and burnished into perfection. He laboured at his work with all his energy, yet desired the world to believe that it was dashed off in bursts of enthusiasm and sent in hot haste to the printers. The life story of the man does not inspire admiration; he is best studied in his works.

Preece, Sir William Henry

b. Carnarvon, February 15, 1834.

Though he inclined more to music than to science, it was in electricity and its many applications to practical affairs that he was destined to distinguish himself. He played an important part in the development of the telegraph in Britain and in the Colonies, and, as Consulting Engineer to the Post Office, was responsible for innumerable inventions of importance. He invented a system of wireless telegraphy ten years before that of Marconi was announced; he adapted electricity in many ingenious ways to the purposes of railway work—not only as to signals, but as a motive power—and has edited quite a library of the literature of the science to which he has devoted his days. He introduced the telephone and the phonograph into Britain, and gave us the first of wireless telephones.

Prescott, William Hickling

b. Salem, Mass., May 4, 1796. d. Boston, January 28, 1859.

While he was studying at Harvard he was deprived, through an accident, of the sight of one of his eyes, but the calamity did not keep him from unremitting study to qualify himself for the task of the historian. He employed a reader, and devised a special apparatus to assist him in his work, and, though practically blind, he produced works of lasting fame on Spanish history, on Mexico, and on Peru. He was still toiling at his history of the reign of Philip II. when overtaken by death.

Priestley, Joseph

b. Leeds, March 13, 1733. d. Northumberland, Pa., February 6, 1804.

The son of a cloth-dresser, he was successively Dissenting minister, school teacher, and librarian. In the latter capacity he served Lord Shelburne, whom he accompanied on a journey to the Continent. There he met Lavoisier and other great chemists, and communicated to them his discovery of oxygen. In their hands this discovery revolutionised chemistry. Disciples of Lavoisier claim for their master that he discovered oxygen and the composition of water independently of Priestley, but the Englishman's title to credit seems clear, though Lavoisier gave oxygen its name. Priestley had called it "dephlogisted air," believing the gas to be air deprived of the so-called phlogiston, in which he believed to the end. He made many other important discoveries, but left to others their correct interpretation. Cavendish laid the foundation of pneumatic chemistry, but Priestley so improved upon his apparatus as to be called the father of pneumatic chemistry. His religious views were generally regarded as heterodox, and towards the close of his career he emigrated to America, there to await the second coming of Christ.

Prior, Matthew

b. East Dorset, July 21, 1664. d. Wimpole, Cambs, September, 18, 1721.

Left fatherless at an early age, he became bookkeeper to his uncle, a vintner, but was befriended by the Earl of Dorset, and enabled to study at Cambridge. Although he is best remembered by his literary productions, in which occur lyrics and epigrams of surpassing excellence, he filled many diplomatic and State offices, and succeeded Locke as Commissioner of Trade and Plantations. His politics brought him to grief, the ascendancy of his enemies leading to his impeachment and incarceration (1715-1717) in gaol.

Ptolemy

b. Alexandria, 2nd century, A.D. d. Alexandria, about 160 A.D.

Although Claudius Ptolemæus borrowed more from the works of Hipparchus than he acknowledged, he was the author of much important independent discovery in astronomy and optics. With the scanty data at his disposal he came to the conclusion that the earth is the centre of the universe, with the heavenly bodies revolving around it. His theories held good until the system of Copernicus upset them. As a geographer he filled an important place. His calculations were often erroneous, but, considering the meagre character of his information, they were remarkably good guesses. One respect in which he was at fault was in his estimate of the circumference of the globe. Columbus, basing his calculations on Ptolemy's works, supposed the distance from the western coast of America to the eastern coast of Asia to be one-third less than is actually the case, and in that belief was encouraged to attempt the voyage which led him to the discovery of America.

Purcell, Henry

b. London, 1658. d. Westminster, Nov. 21, 1695.

Admitted as a chorister of the Chapel Royal, he composed an ode, when only twelve years of age, on the King's birthday; and he was but seventeen when he gave to the world his notable opera, "Dido and Æneas." He wrote much fine church and chamber concert music, as well as composition for less formal use, and in every respect surpassed all predecessors in this country. His music is still popular, more than two centuries after his death.

Purchas, Samuel
b. Thaxted, Essex, 1577. d. London, September, 1626.

A clergyman, he compiled books of travel which possess the highest historical value. During the latter part of his career he was Rector of St. Martin's, Ludgate Hill.

Puschkin, Alexander Sergejevich
b. Moscow, May 26, 1799. d. St. Petersburg, January 29, 1837.

Puschkin was one of the greatest of Russian poets, the son of a woman of negro descent. Although his political views were far in advance of his age in Russia, he was repeatedly employed in the administrative work of the Government, but after a semi-exile he was dismissed and confined to his estate. He died of wounds sustained in a duel.

Pythagoras
b. Samos, Greece, about 580 B.C. d. Crotona, about 500 B.C.

He was a famous philosopher, and founder of the school of philosophy called after his name. He left no writings, our knowledge of his teachings and institutions depending on the traditions of his disciples.

Quincey, Thomas de
b. Manchester, August 15, 1785. d. Edinburgh, December 8, 1859.

This brilliant essayist and miscellaneous writer was the son of a wealthy linendraper, but, owing to his erratic conduct as a youth, had to undergo severe privations in London before going to Oxford University. Here he contracted the opium habit, and upon his weakness based his famous "Confessions of an English Opium-eater," which at once established his reputation. His many charming writings were contributed, for the most part, to magazines, and not published in book form until shortly before his death. He long shared the friendship in the Lakes of Coleridge and Wordsworth.

Racine, Jean Baptiste
b. La Ferté-Milon, France, December 21, 1639. d. Paris, April 21, 1699.

The greatest of French tragic poets was left an orphan at an early age, but was carefully educated by his grandparents, and received into the best literary society of his age. His literary career began with the publication of odes, but his friendship with men like La Fontaine, Boileau, and Molière led him to devote himself to the drama. In this he achieved striking successes, until either successful rivalry or his conversion to religion turned him finally to poetry. As a poet he was even greater than as a dramatist, and bequeathed to posterity some of the most exquisite melody in words ever conceived by the mind of man.

Raikes, Robert
b. Gloucester, September 14, 1735. d. Gloucester, April 5, 1811.

Moved by compassion for the desperate lot of the children of the poor, he started a Sunday-school in Gloucester, at which they were taught to read and write and instructed in the Christian faith. The first of its kind ever established, it was a success from the outset, and became the parent of the entire Sunday-school movement. Raikes was a newspaper owner.

Raleigh, Sir Walter
b. near Sidmouth, Devon, 1552. d. London, October 29, 1618.

One of the towering figures of Elizabethan days, Raleigh had all the daring and imagination of the hero of romance. He was a brilliant and daring soldier, a dauntless explorer, a polished statesman and courtier, a distinguished scientist and author. After completing his education at Oxford, he served five years abroad as a volunteer in aid of the Huguenots, then took part in the expedition to America. He gained the favour of Elizabeth, who heaped riches and honours upon him. His attempt to colonise that portion of America to which she gave the name of Virginia cost Raleigh £40,000, and yielded to England at the outset tobacco and the potato. Raleigh was ever the foe of Spain, and had a brave part in the destruction of the Armada, and in many lesser engagements with the great Catholic nation in the Old World and the New. Threatened in the affections of Elizabeth by the handsome and gallant Essex, Raleigh repaired to Ireland, where the Queen had given him an estate of 40,000 acres. He was soon restored to favour by the Queen, who would have made Raleigh's career more glorious had she not so dotingly kept him at Court when he was planning greater enterprises. However, his favour ended when his intrigue with Bessy Throckmorton was discovered. Tales of the riches of Guiana drew Raleigh from retirement, and he set sail on an expedition of discovery, and published an account of his doings. With the accession of James I. Raleigh was accused of treason, and condemned to death. For long he was kept a prisoner, then was released, to go again to Guiana. His expedition failed, and upon his return he was re-arrested and executed.

Ramsay, Sir William
b. Glasgow, October 2, 1852.

One of the most distinguished of modern scientists, he was educated at Glasgow, and Tübingen Universities, and, after a successful career as tutor and college principal, won renown by researches into the constituents of air. In conjunction with Lord Rayleigh, he discovered argon. Besides the discovery of helium, he has identified and measured the previously unknown elements in the air, which he has named neon, krypton, and xenon. Awarded the Nobel prize in chemistry in 1904, he has been honoured by practically all the most famous learned and scientific bodies of Europe.

Ranke, Leopold von
b. Wiehe, Germany, December 21, 1795. d. Berlin, May 23, 1886.

Educated at Leipsic, he held professional appointments at Berlin, became historiographer of Prussia, and wrote many notable volumes on history. His works are distinguished by their statesmanlike breadth of view, but they rather neglect the social side of national development.

Raphael (or Raffaello Sanzio)
b. Urbino, Italy, March 28, 1483. d. Rome, April 6, 1520.

The prince of painters was the son of a poet and painter, and from an early age began the study of art, under his father and Vito; then, after the death of the former, under Perugino. The latter he excelled, and, going to Florence at twenty-one, was ripe for the influence of Michael Angelo and Leonardo da Vinci. For four years he lived in this atmosphere of supreme art, and executed some of the noblest of his works. Invited to Rome by Pope Julius II., he spent there the last twelve years of his life, and in that time produced an amazing number of works. It was as if he foresaw that his years were to be few—he died at thirty-seven—and that he must labour with all haste. Hard as he worked, he never permitted any of his pictures to suffer from lack of due care. He erred, indeed, in the opposite direction, seeking to combine too many perfections, and falling short of his own best. He left an enormous number of paintings, portraits, studies, drawings, sketches, and studies. Besides this, he was a sculptor of high ability, and acted as master architect of St. Peter's at Rome, in addition to superintending the excavation of antiquities. A man of many friendships, to the end he was unspoiled by his success, and was said to be beloved not only by all men, but by the very brutes.

Ray, John
b. near Braintree, Essex, November 29, 1627. d. near Braintree, January 17, 1705.

The son of a blacksmith, he became a *Fellow* of Trinity College, and devoted himself to natural history. His classification of plants was the foundation of the "natural system"; his zoological works were the basis of all modern zoology.

Rayleigh, John William Strutt, Lord
b. Witham, Essex, November 12, 1842.

At Cambridge he was the Senior Wrangler and Smith's Prizeman, and became, at thirty-seven, Professor of Experimental Physics there, and afterwards succeeded Tyndale as Professor of Natural Philosophy at the Royal Institution. His most popular work was the discovery, with Sir William Ramsay, of argon; but his labours in the whole field of science have been of the greatest importance in many directions. He has not hesitated to go again over ground broken by others, and the result has been that either he has said the final word upon the subjects, or opened up entirely new horizons of discovery.

Rembrandt, Hermanszoon van Rhyn
b. Leyden, Holland, July 15, 1607. d. Amsterdam, October 8, 1669.

His father was a prosperous miller, and he was afforded a good education, though his art was mainly self-developed. He showed much independence of convention and example, and went to Nature for his inspiration. His works became famous until disaster overtook him. His wife, who had brought him a fortune, died; then he became bankrupt, and saw all his treasures sold. His closing years were passed in poverty and wretchedness. He toiled incessantly, but his art had declined in popularity, and the creator of some of the noblest works in existence had to be buried at the public expense.

Rennie, John
b. East Lothian, June 7, 1761 d. London, October 4, 1821.

He began life as a millwright, but by great diligence became one of the foremost engineers of the age. The Southwark, Waterloo, and London bridges were built from his plans while he designed the London Docks, the India Docks, and others in the provinces, as well as the dockyards at Portsmouth, Chatham, Sheerness, and Plymouth.

Reynolds, Sir Joshua
b. near Plymouth, July 16, 1723. d. London, February 23, 1792.

Educated by his father, a schoolmaster and clergyman, he afterwards studied painting in London and at Rome. Then he caught a chill, which rendered him deaf. Returning to London, he rapidly established a high reputation as a painter, and upon the formation of the Royal Academy became its first president. In the following year he began his famous "Discourses" to the students. Three years before his death his sight failed, and he was compelled to relinquish painting. His portraits placed him at the head of the English school of portrait-painting, in which he has never been surpassed. He enjoyed the friendship of the literary lions of his time, and founded the Literary Club, which had among its members Johnson, Garrick, Burke, Goldsmith, Boswell, and Sheridan.

Rhodes, Cecil John
b. Bishop-Stortford, July 5, 1853. d. near Cape Town, March 26, 1902.

A son of the rectory, he went as an invalid in search of health to Natal, and remained, to make a fortune from the Kimberley diamond-mines. But, while he was making himself one of the richest men in the world, he was dreaming dreams of empire—of a stretch of country, "all British," from the Cape to the Zambesi. He returned to England, and took his B.A. and M.A. at Oxford University, and was for a time a law student. While South Africa was developing, he financed many undertakings which were making for progress, entered the Cape Parliament, and was hopeful enough of the future to decline the invitation of his friend, General Gordon, to accompany him to Khartoum. Foiled by the Cape Parliament in the attempt to take over a large part of Bechuanaland, he was more successful with the Imperial Government, by which he was appointed Deputy Commissioner for the new Protectorate. Events marched quickly now. He consolidated the various diamond-mining companies at Kimberley, became Premier of the Cape Parliament, and secured a charter for the British South Africa Company, whose territory is now known as Rhodesia. The Jameson Raid into the Transvaal, in 1896, checked his political career, but not his imperial projects. To the end he was actively engaged in furthering his scheme for making homes in South Africa for the British colonists. He died of heart disease, the complaint from which all his life he had suffered. His will is a notable document. It includes bequests to Oxford University, and provides scholarships for English-speaking students from various parts of the world.

Richardson, Samuel
b. Derbyshire, 1689. d. London, July 4, 1761.

The father of the English domestic novel was the son of a carpenter and joiner, and was apprenticed to a London printer. His proficiency with his pen in an age when penmanship was a rare art among the lower classes led to his frequent employment by young people desiring to correspond with their sweethearts and relatives. This practice gave him an insight into the ways and needs of humble life, and led to his publishing his first book—a volume for the instruction in letter-writing of the illiterate. The same didactic scheme prompted the writing of his novel "Pamela," which he designed "to cultivate the principles of religion and virtue in both sexes." The book had a remarkable vogue, and encouraged him to patient effort in the production of his masterpiece, "Clarissa Harlowe," which Johnson declared to be the first book in the world for its knowledge of the human heart.

Richelieu, Armand Jean Duplessis, Cardinal, Duc de
b. Poitou, France, September 5, 1585. d. Paris, December 4, 1642.

Born a son of the Grand Provost of France, he aspired to a military career, but upon his brother throwing up his bishopric to become a Carthusian, the younger Richelieu had to succeed him, and so did, when twenty-two. In 1614 the States General, which was not again to be convoked until 1789, assembled, with Richelieu as a deputy from Poitou. His support of the queen-mother, Mary de Medici, led to her appointing him as her grand almoner, and his political career had begun. He rose to the position of Secretary of State, but fell when she retired to Blois, and accompanied her thither. He succeeded in reconciling the queen and her son, Louis XIII., and was appointed Minister by the latter. Thenceforth Richelieu was virtually King of France. He crushed the plotting nobles, who were battening like birds of prey upon the country; he destroyed the political power of the Huguenots, struck heavy blows at Spain and Austria, and vastly extended French influence. A prince of schemers himself, he was constantly plotted against, and was seldom free from danger. Personal ambition had no part in his procedure. He sought to enhance the prestige of his country by strengthening the Crown. All constitutional government and all vestiges of local liberty were destroyed. He was merciless and implacable, but it was against the most powerful foes of his country that his blows were chiefly aimed. He prepared the way for the Revolution.

Richter, Jean Paul Friedrich
b. Wunsiedel, Bavaria, March 21, 1763. d. Bayreuth, November 14, 1825.

A famous humorist, and one of the most gifted of German writers, he had a long and hard struggle with fortune before winning recognition. His first writings were a failure, and he had to earn his bread by teaching while writing works which were to make him one of the most famous men of his era. Success having once come to him, it stayed, and he was almost idolised by his generation.

Ridley, Nicholas
b. Haltwhistle, Northumberland, about 1500. d. Oxford, Oct. 16, 1555.

After studying at Cambridge and on the Continent, he became domestic chaplain to Cranmer and Henry VIII., Bishop of Rochester, and finally Bishop of London. An ardent advocate of the Reformation, he was arrested under Mary, and after a long imprisonment was, with Latimer, burned as an obstinate heretic.

Rodin, Auguste
b. Paris, Nov., 1840.

Although receiving an artistic training, he had in early manhood to engage in menial labour for a livelihood, but became famous at once with the bust called "The Broken Nose," which was exhibited when the sculptor was only twenty-three. Like other great artists, he has not always had the critics on his side, but later years have brought him indisputably to the head of his profession.

Rodney, George Brydges, Lord
b. Walton-on-Thames, Feb. 19, 1719. d. London, May 24, 1792.

He served in the Seven Years War, gained a great victory over the Spaniards at Cape St. Vincent, captured Martinique, St. Lucia, and Grenada, and, by defeating the French at Havre, destroyed the flotilla by which it had been intended to invade England.

Romilly, Sir Samuel
b. London, March 1, 1757. d. London, Nov. 2, 1818.

The son of a watchmaker, he became a great lawyer, and attained to the position of Solicitor-General. He is famous for his untiring efforts to reform the criminal law of England, which, in his day, was a barbarous code, including capital punishment for comparatively trivial offences. When sixty-one he lost his wife, and was so distressed at her death that he took his own life.

Romney, George
b. Dalton, Lancs, Dec. 15 1734. d. Kendal, Nov. 15, 1802.

He joined his father in the workshop as a cabinet-maker, but showed unmistakable evidence of genius as an artist, and eventually became one of the most distinguished of English portrait-painters. The most famous of his works are his portraits of Lady Hamilton. His paintings have increased in value to thirty or more times the prices which he obtained.

Ronalds, Sir Francis
b. London, Feb. 1788. d. Battle, Aug. 8, 1873.

A London merchant's son, he early interested himself in mechanics and electricity, invented an electric telegraph, and established it, with eight miles of insulated wire, in his garden at Hammersmith. He offered to demonstrate his invention before the Admiralty, but was answered: "Telegraphs of any kind are now totally unnecessary, and no other than the one now in use will be adopted." The one then in use was the old semaphore. He bore his rebuff with much good-humour, bade "a cordial adieu" to electricity, and set himself to the invention of an instrument which has proved invaluable to meteorologists and physicists. Wheatstone and Cook afterwards developed the Ronalds telegraph, and had it publicly used twenty-one years after he had offered it to the Admiralty.

Rontgen, William Konrad von
b. Lennep, Germany. March 27, 1845.

He was trained in Holland and at Zürich, and began to teach at Würzburg and Strasburg. At the former place, while experimenting with a highly-exhausted vacuum tube on the conduction of electricity through gases, he discovered the famous X-rays, now called, in his honour, Röntgen rays. He has distinguished himself in other branches of science, but it is by this discovery that he is popularly known to the world.

Rosa, Salvator
b. nr. Naples, June 20, 1615. d. Rome, March 15, 1673.

Intended for the Church, he devoted himself to musical composition, but by frequenting the studio of his brother-in-law became imbued with a love of art, and adopted painting as a profession. After working for some time in obscurity, he attained fame with his picture, "Tityrus tortured by the Vulture"; and, removing to Rome, raised himself to independence and celebrity. He was gifted as poet and satirist, as well as musician and painter, and his writings are still read. In art he was distinguished by the gloomy grandeur and terrible magnificence of his pictures.

Salt, Sir Titus
b. Morley, Yorks, Sep. 20, 1803. d. Saltaire, Yorks, Dec. 29, 1876.

The son of a cloth manufacturer who turned farmer. Salt was brought up to the trade of a wool-stapler, and invented a process for turning to profit alpaca, a fabric which had previously defied all efforts to render it saleable. Salt accomplished with alpaca as great wonders as Lord Masham achieved with silk-waste, and founded the model manufacturing town of Saltaire for his works and workpeople.

Sand, George
b. Paris, July 2, 1804. d. Nohant, France, June 7, 1876.

"George Sand" was the assumed name of Amantine Lucile Aurore Dupin, Baroness Dudevant, novelist, playwright, and miscellaneous writer. Married at eighteen, she quitted her husband for the Bohemian literary life of Paris, where among her intimates were Jules Sandeau, Alfred de Musset, and Chopin.

Sappho
b. Mytilene (?), Asia Minor, 7th Century, B.C.

Just as "The Poet" served as sufficient description of Homer, so "The Poetess" was the description of Sappho, one of the greatest of Greek lyrists. Only two of her odes, and about 150 scattered, broken lines remain, but by ancient writers and modern she is proclaimed the only poet whose every word has a seal of absolute perfection and inimitable grace.

Sargent, John Singer
b. Florence, 1856.

The son of an American physician, he grew up in an artistic atmosphere, and, trained by Carolus Duran, has developed into one of the foremost portrait and genre painters of the age.

Saunderson, Nicholas
b. Thurlston, Yorks, Jan., 1682. d. Boxworth, Cambs. April 19, 1739.

Although blind from infancy, he became an accomplished scholar and famous as a lecturer at Cambridge University, whither he was taken as a poor student by a sympathetic friend.

Savonarola, Girolamo
b. Ferrara, Italy, Sep. 21, 1452. d. Florence, May 23, 1498.

First a Dominican monk and later prior of St. Mark's, Florence, he had enormous influence by his fearless denunciation of the vice and corruption in Church and State. He brought about a great religious revival and led to the overthrow of the Medici, but the lasting animosity of Pope Alexander VI., whom he had assailed, brought his arrest and barbarous execution.

Schule, Karl Wilhelm
b. Stralsund, Dec. 2, 1742. d. Koping, Sweden, May, 1786.

While serving as a chemist's apprentice, and afterwards as a pharmist, he made an unparalleled series of discoveries, in the course of which, independently of Priestley, he discovered oxygen and nitrogen. Among his many other discoveries were: Oxalic, tartaric, citric, lactic, and arsenic acids and their salts; baryta and the salts of barium; uric acid and the composition of prussic acid and Prussian blue.

Schiller, Johann, Christoph Friedrich von

b. Marbach, Germany, Nov. 10, 1759. d. Weimar, May 9, 1805.

The son of an army surgeon, he first tried the law, but turned to medicine, and entered the army as a surgeon. But the pen early claimed his affections, and at twenty-three he was in disgrace for a play of revolutionary tone. He fled from Stuttgart, and though afterwards his successes as dramatist and poet were second to those of no other man of his age, he and poverty were never for long strangers. Philosophy and poetry are admirably blended in his works. With Goethe he succeeded in elevating the German drama and in moulding and purifying the thought and language of a great people.

Schubert, Franz Peter

b. Vienna, Jan. 31, 1797. d. Vienna, Nov. 19, 1828.

The son of a musician, he early showed a genius for composition, but the times were not propitious, and the privations which he suffered during youth brought him to an early grave. He composed 500 songs, among which are some of the loveliest in existence, ten symphonies, six masses, several operas, cantatas and overtures, and a host of sonatas and other compositions.

Schumann, Robert

b. Zwickau, Saxony, June 8, 1810. d. near Bonn, Germany, July 29, 1856.

He did not take up the study of music until twenty-one years of age, but two years later he published his first important composition, and in the following year began his writings on music. His subsequent career was chequered. Beautiful compositions were followed by spells of madness, and he died in an asylum for the insane. His music is distinguished by freshness and originality, much piquancy in rhythm and wealth and resource in harmony.

Scipio, Publius Cornelius Africanus Major

b. 237 B.C. d. Campania, Italy, 183 B.C.

A soldier from his youth up, he gained great successes for the Roman arms, and caused the recall of Hannibal from his invasion of Italy to defend Carthage. Scipio inflicted upon him his only defeat, and ended the second Punic War.

Scott, Sir Walter

b. Edinburgh, Aug. 15, 1771. d. Abbotsford, Sep. 21, 1832.

An early illness, though it left him lame for life, was a blessing in disguise, for he was given the run of an ample library, there to store his mind with reading which no ordinary boy would have attempted. Brought up to the law, as his father had been, he first became known by translations of German writings, following this with poems of his own. His original poems speedily brought him fame, and fearing that he might sacrifice this if he appeared as a novelist, he published the early volumes of the immortal "Waverley" novels anonymously, and stoutly denied the authorship when challenged. Not until twenty-five of them had appeared did he publicly admit their parentage. A secret partnership with the Ballantynes proved an inauspicious venture, and upon Constable taking over the business and failing, Scott became involved in a loss of £120,000, in addition to £30,000 private debt. His declining years were devoted to paying off this sum, and in the end, after his death, every creditor had his due. Not only did Scott write poems and novels and a vast number of miscellaneous articles; he edited large editions of Dryden and Swift, and wrote a nine-volume "Life of Napoleon." His baronetcy was conferred by George IV., of whom the Jacobite genius was, paradoxically enough, an ardent admirer.

Selden, John

b. Salvington, Sussex, Dec. 16, 1584. d. London, Nov. 30, 1654.

A poor boy, bred to the law, he became a successful lawyer, but found time for wide and profound study, and for the production of deeply learned historical, antiquarian, and legal works. His resolute stand for liberty caused him to be imprisoned for nearly a year in the Tower, without, however, abating his zeal for the right. He helped to draw up the Petition of Right, but did not take part in the impeachment of Strafford or in Laud's prosecution, while he was opposed to the execution of Charles I.

Shaftesbury, Anthony Ashley Cooper, 7th Earl of

b. London, April 28, 1801. d. Folkestone, Oct. 1, 1885.

While still a schoolboy he determined to devote his life to ameliorating the condition of the poor. He helped to reform the law in its relation to the treatment of lunatics, for the prevention of the employment of boys as chimney-sweeps, and for the Factory and Workshop Regulation Acts. He was a devoted friend of the Ragged School movement, and was a foremost figure in all the social reforms effected during his lifetime.

Shakespeare, William

b. Stratford on Avon, Ap. 23 (?), 1564. d. Stratford on Avon, Ap. 23, 1616.

The greatest of dramatists and one of the most gifted of poets had for his father a fellmonger and glover, while his mother was a woman of some fortune. Comparatively little is known of his life. A reverse in the fortunes of his father compelled him to take service, with but scanty store of education, as apprentice to a butcher, while there is a tradition as to his being employed in the office of an attorney. Married, while a youth, to Anne Hathaway, he was the father of a daughter at nineteen, and a few years later quitted his native town, impelled, it is supposed, by a prosecution for deer-stealing. His early life in London is obscure, but it is supposed that at the outset he earned a livelihood by holding horses near the spot where he was to gain more or less renown as an actor in his own plays. The first of these, preceded by the poems "Venus and Adonis" and "Lucrece," was probably "Love's Labour's Lost," followed by the "Comedy of Errors," "Two Gentlemen of Verona," and "A Midsummer Night's Dream." Play followed play with amazing rapidity, the author's genius developing in new directions with each production. "The Merry Wives of Windsor" is said to have been hastily produced in compliance with Queen Elizabeth's command that he should exhibit Falstaff in love. Shakespeare was by this time a prosperous man. He wrote for the hour, not for posterity.

"For gain, not glory, wing'd his roving flight,
And grew immortal in his own despite."

His raw material for comedy and historical drama and tragedy he took from various sources—old plays, old chronicles, the writers of antiquity. "The Winter's Tale" dramatises a novel. He bought a residence at Stratford and another in London, and died at the former in his forty-ninth year. Seven years elapsed between his death and the appearance of the first collected edition of his works, and scholars to this day are not able to say quite where his pen ceased and others began. The mystery is little less perplexing than that by which the works of Homer are invested. But those works, wholly his, or touched here and there by the hand of a collaborator, remain the chief literary heritage of the Anglo-Saxon race, even if Landor spake not truly when he said "Shakespeare is not our poet, but the world's!"

Shelley, Percy Bysshe
b. near Horsham, Sussex, Aug. 4, 1792. d. Spezzia Bay, Italy, July 8, 1822.

Expelled from Oxford University for an atheistical pamphlet, Shelley, out of chivalrous desire to save from suicide the daughter of a coffeehouse-keeper, married her. He was nineteen, she was seventeen. They parted three years afterwards, and he went to Switzerland with Mary, daughter of William Godwin, whom, upon the suicide of his wife, he married. The second union was productive of much happiness for the poet, whose finest work was now produced. He was drowned while sailing in the Bay of Spezzia, and his body, recovered eleven days later, was burned upon the shore in the presence of his friends Trelawny, Leigh Hunt, and Byron.

Sidney, Sir Philip
b. Penshurst, Kent, Nov. 29, 1554. d. Zutphen, Holland, Oct. 17, 1586.

Warrior, statesman, poet, he experienced the full force of a capricious queen's power to wound a subject, and met his death in an expedition against the Netherlands, undertaken for policy's sake at Elizabeth's behest. His literary masterpieces were unknown to the world at large during his lifetime, for, though celebrated in Court circles, they were not published until after his death. His writings have proved a well of inspiration at which many later poets have drunk deep; his career was a pattern to all who strive to live the life of a true gentleman.

Siemens, Ernst Werner
b. Lenthe, Germany, Dec. 13, 1816. d. Berlin, Dec. 6, 1892.

After fifteen years' service in the Prussian Army, he established works for carrying out many of the electrical inventions with which his fertile brain teemed.

Siemens, Sir William
b. Lenthe, Germany, April 4, 1823. d. London, Nov. 19, 1883.

The younger and more distinguished of the Siemens brothers came to England poor in pocket, but rich in scientific knowledge, and after many trials, established a great and successful business. Naturalised, he was the recipient of many distinctions for his inventions in metallurgy, and contributed works of great value to the scientific literature of the period. He and his brother generously helped the movement for the better education of aspirants to careers in science.

Simpson, Sir James Young
b. Bathgate, Scotland, June 7, 1811. d. Edinburgh, May 6, 1870.

The first man to introduce anæsthetics into British surgery was the son of a humble baker. He made many experiments before discovering the value of chloroform for his purpose, and fought a long fight against bigotry and prejudice before making his practice popular.

Smith, Adam
b. Kirkcaldy, June 5, 1723. d. Edinburgh, July 17, 1790.

After study at Glasgow and Oxford and filling professorial chairs at Edinburgh, he travelled as tutor to the Duke of Buccleuch, then settled down to studious retirement and the production of his famous works on political economy. Of these the "Wealth of Nations" remains still the economists' guide and source of inspiration.

Socrates
b. Athens, about 470 B.C. d. Athens, 399 B.C.

After following the calling of his father, that of a sculptor, Socrates gave himself up entirely to the study of philosophy, which he taught and expounded to such famous pupils as Plato, Xenophon, and Alcibiades. His life was one long campaign for truth and virtue. In his old age his enemies charged him with impiety and with corrupting the morals of the youth of Greece. He defended himself in a noble speech, but the verdict of partial judges going against him, he drank hemlock in his cell, surrounded by his disciples.

Sophocles
b. nr. Athens, 496 B.C. d. Athens, 405 B.C.

One of the three great tragic poets of ancient Greece, he defeated Æschylus, his elder by thirty years, in a tragic competition when twenty-eight years of age, and reigned supreme until Euripides was preferred, in 441. Although he discharged missions of State, his heart was always in his poetry, and he bequeathed to the world some of the masterpieces of human genius.

Speke, John Hanning
b. Ilminster, May 4, 1827. d. Bath, Sep. 15, 1864.

After service with the Indian Army, he explored the Equatorial lakes of Africa in company with Burton. While travelling alone he discovered the Victoria Nyanza, and in it the long-sought source of the Nile.

Spencer, Herbert
b. Derby, April 27, 1820. d. Dec. 8, 1903.

His father, a schoolmaster, intended him to follow the occupation of a railway-engineer, but Spencer threw up this calling for that of letters, and from early manhood began to develop the ideas which were eventually to issue in his System of Synthetic Philosophy. His writings have had a profound influence upon the thought of his own country, and an even greater effect upon foreign peoples, into whose languages they have been translated.

Spenser, Edmund
b. London, about 1552. d. London, Jan. 13, 1599.

Born of poor parents but good family, he proceeded from Merchant Taylors' School to Cambridge University. Winning the friendship of Sir Philip Sidney, to whom he dedicated his "Shepherd's Calendar," he was appointed, through Sidney's uncle, Lord Leicester, private secretary to Lord Grey de Wilton when the latter was sent to repress the rebellion in Ireland. Before crossing over, Spenser had begun his "Faerie Queen," and continued at his task in Ireland amid fierce fighting and plots culminating in the destruction of his own home there. Although he enjoyed great literary fame, his fortunes were of the most dismal character, and he died in London utterly destitute.

Spinoza, Benedict Baruch
b. Amsterdam, Nov. 24, 1632. d. The Hague, Feb. 21, 1677.

Excommunicated by the Jewish community, of which he was a member, he supported himself by grinding lenses, so that he might compose his works on philosophy and pantheism, which were destined to form the acknowledged basis of much of modern German philosophy.

Stanley, Sir Henry Morton
b. Denbigh, Wales, 1841. d. London, May 10, 1904.

His name was Rowlands, but on making his way from his poverty-stricken home to New Orleans, he adopted the name of an American Stanley, who befriended him. On growing up, he fought in the American Civil War, turned newspaper correspondent, and was sent on behalf of an American newspaper to the Abyssinian War. He so impressed his employer that later he was commissioned to head an expedition into Africa in search of Livingstone. This mission he accomplished, and afterwards made important explorations, and established for the King of the Belgians the Congo Free State. From another of his expeditions the British East Africa Company developed; while his final and not least notable journey through the Dark Continent was undertaken for the relief of Emin Pacha. Stanley married the skilful artist, Miss Dorothy Tennant, who survives him.

Steel, Sir Richard

b. Dublin, March 1672. d. nr. Carmarthen, Sep 1, 1720.

Soldier, member of Parliament, political pamphleteer, playwright, Steel is one of the few men whose newspaper writings have become immortal. His collaboration with Addison in the "Tatler" and "Spectator" was most happy, though the two friends ultimately quarrelled.

Stephenson, George

b. nr. Newcastle, June 9, 1781. d. nr. Chesterfield, Aug. 12, 1848.

First a farm-hand, next fireman at a colliery, he devoted his pocket-money as a youth to learning to read and write and sum. His first notable invention was a safety lamp for miners. Next came his first steam-engine, rendered successful by his later invention of the steam-blast. Upon becoming engineer for the first railway, he constructed the famous "Rocket" locomotive. He attained to great prosperity, and was employed on many important schemes during the race for railways which followed. His son, ROBERT STEPHENSON (b. Oct. 16, 1803. d. Oct. 12, 1859), won independent renown by the construction of many famous railway and other bridges.

Stevenson, Robert Louis Balfour

b. Edinburgh, Nov 13, 1850 d. Samoa, Dec. 3, 1894

Intended for the law, he never practised, but travelled by strange methods, and turned his experiences to account in some of the most charming writings in the language. He was equally distinguished as essayist and author of fiction, while much of his verse is admirable.

Strabo

b. Amasia, Pontus, about 63 B.C. d. about 21 A.D.

Little is known of the greatest geographer of antiquity, except from the record of his travels. These embraced visits to Greece and Italy, Egypt, up the Nile, Africa, and Asia Minor. His work "surpasses all the other geographical writings of antiquity, both in grandeur of plan and in the abundance and variety of its materials." Many of his estimates of the size and configuration of the world were hopelessly wrong, but the performance was very wonderful, his scanty resources considered.

Sullivan, Sir Arthur Seymour

b. London, May 13, 1842. d. London, Nov. 22, 1900.

He began his musical career as a choir-boy, studied at Leipzig, and at twenty years of age had made his name as a composer. Cantatas and oratorios, tuneful songs, and hymn-tunes, now famous wherever religious music is heard, followed. His most famous achievements, however, were the delightful comic operas which he produced in collaboration with Sir F. S. Gilbert.

Swedenborg, Emanuel

b. Stockholm, Jan. 29, 1688. d. London, March 29, 1772.

Distinguished as a scholar and military engineer, he wrote several works on natural philosophy before he began to dream dreams and see visions and to expound the Christian faith as it appeared to him. The Swedenborgian Church was established sixteen years after his death.

Swift, Jonathan

b. Dublin, Nov. 30, 1667. d. Dublin, Oct. 19, 1745.

The British Rabelais was first a power in the Whig Press, and afterwards one of the most trenchant writers on the other side. In addition to minor incumbencies held earlier, he was Dean of St. Patrick's, Dublin, for over thirty years. Much of his time was spent in London society prior to this appointment, but it was while in Ireland that he wrote most of his famous satires. His days were clouded by periods of madness, which condition, indeed, throughout the greater part of his life, he was frequently bordering. A strange fact is that "Gulliver's Travels," his supreme satire upon the cant and shams of the age, has become a children's classic.

Swinburne, Algernon Charles

b. London, April 5, 1837.

Son of an admiral, he quitted Oxford without a degree and travelled on the Continent, when he was the guest of Landor. His poems, which give him undisputed supremacy as a master of metrical invention, include some of the most exquisite lyrics in the language, while his prose writings are characterised by a vigour and charm of exceptional character. By common consent, he was the only poet worthy to succeed Tennyson as Poet Laureate.

Tacitus, Cornelius

b. Rome, about 52 A.D. d. Rome, about 117 A.D.

"The greatest man who has yet given himself to the recording of human affairs," as Froude describes him, was first famous as a legal orator. He married the daughter of Agricola, conqueror of Britain, and held offices under the State.

Tasman, Abel Janssen

b. Hoorn, Holland, about 1602 d. Batavia, Oct. 1659.

Despatched by Van Diemen, Governor of the Dutch East Indies, to seek "the great South Land," he discovered Tasmania (calling it Van Diemen's Land), New Zealand, part of the Friendly Islands, and ultimately the Bay of Carpentaria.

Tasso, Torquato

b. Sorrento, Italy, March 11, 1544. d. Rome, April 25, 1595.

Finding the pursuit of law and philosophy distasteful, he succeeded, by the production of a romantic poem, in persuading his father to let him follow his bent for letters. His noble epic, "Jerusalem Delivered," was followed by a mental breakdown. He imagined his rich and powerful friends to be his enemies, and had to undergo seven years' detention in a lunatic asylum. During his incarceration he wrote many noble verses and philosophical dialogues. Although released and able to continue his writings in freedom, he never wholly recovered, and died on being summoned to Rome to be crowned Poet Laureate.

Tennyson, Alfred Lord

b. Somersby, Lincs, Aug. 6, 1809 d. Aldworth, Sussex, Oct. 6, 1892.

One of a Lincolnshire rector's sons, of whom two besides himself were poets, Alfred Tennyson wrote verse as soon as he could write anything. He completed his education at Cambridge. The bulk of his loveliest lyrics were written before he passed his thirtieth year, and at forty-two he was promoted Poet Laureate, in succession to Wordsworth. In 1850 he published "In Memoriam," which, with the "Idylls of the King," constitute his noblest work. His poetical dramas, some of which were played in his own time, were of later date. His career ensured by a pension bestowed while he was yet young, his lot was happier far than that which usually falls to a great poet. He was created a baron when seventy-five.

Tesla, Nikola

b. Smiljan, Servia, 1857.

Educated with a view to devoting himself to mathematics and physics, he took up engineering, and has become one of the foremost inventors of electrical appliances.

Thackeray, William Makepeace

b. Calcutta, July 18, 1811. d. London, Dec. 24, 1863.

On his way home from India to England at St. Helena, he caught a glimpse of Napoleon. Educated at Charterhouse and Cambridge, he turned to art, but necessity compelled him to ply his pen for a livelihood. When he and Dickens were young, he asked to be allowed to illustrate "Pickwick," and Dickens refused his offer. Sustained success did not come to Thackeray until towards the end of "Vanity Fair," which was appearing serially. Then it turned completely in his favour. His domestic life was unhappy, his wife's mind giving way during the illness of one of their children.

Themistocles

b. about 525 B.C. d. about 459 B.C.

Famous as a general and statesman, he won for the Athenians the victory of Salamis.

Theocritus

b. Syracuse, 3rd Century B.C. d. Sicily (?), about 250 B.C.

He was the Greek poet of Nature and pastoral life, and his influence is to be traced in the work of many later classics.

Thucydides

b. Athens, about 471 B.C. d. about 401 B.C.

Warrior and scholar, he was condemned to death for his lack of success in the former capacity, but retired into exile and began his immortal work—the first of critical histories.

Titian

b. nr. Venice, about 1477. d. Venice, Aug. 27, 1576.

The chief of the Venetian school of painters and the greatest master of colour that the world has known, he worked for ninety years at his art, and died practically brush in hand.

Torricelli, Evangelista

b. Faenza, Italy, Oct. 15, 1608. d. Florence, Oct. 15, 1647.

His discoveries in relation to the gravity of the air resulted in the barometer, and his experiments with lenses gave us new and better telescopes and the microscope.

Tyndall, John

b. Leighlin Bridge, Ireland, Aug. 21, 1820. d. Haslemere, Surrey, Dec. 4, 1893.

Surveyor and engineer, he distinguished himself as a physicist and scientific author and lecturer.

Van Dyck, Sir Anthony

b. Antwerp, March 22, 1599. d. London, Dec. 9, 1641.

A pupil and asistant of Rubens, he specially distinguished himself by his portraits. His title was conferred by Charles I., by whom he was appointed painter to the English Court.

Velasquez, Diego Rodriquez de Silva y

b. Seville, June 6, 1599. d. Madrid, Aug. 6, 1660.

Velasquez was his mother's maiden name. His "Water Seller" made him famous, and he was taken to the Spanish Court, where he painted scores of works whose glories came as a revelation to later generations, but which in the meantime had remained little known in the gloomy royal galleries of Madrid.

Veronese, Paul

b. Verona, 1528. d. Venice, April 19, 1588.

His real surname was Caliari—Veronese refers to his birthplace. He was the last of the great Venetian painters.

Vespucci, Amerigo

b. Florence, March 9, 1451. d. Seville, Feb. 22, 1512.

The man whose Christian name the American Continent bears was sent by his employers to Spain, and fitted out one, if not two, of Columbus's expeditions. He claimed to have made four voyages to the New World, but there is no record of his actually having done so.

Virchow, Rudolf

b. Schivelbein, Germany, Oct. 13, 1821. d. Berlin, Sep. 5, 1902.

The son of a small shopkeeper, he became famous as a statesman, but infinitely more so as "the father of modern pathology." Among his many famous achievements was the establishing of what Lord Lister calls "the true and fertile doctrine that every morbid structure consists of cells which have been derived from pre-existing cells as a progeny." Of material results, the new Berlin, with its model sanitary system, water supply, and hospitals, is one of his monuments.

Virgil, Publius Virgilius Maro

b. Andes, Italy, Oct. 15, 70 B.C. d. Brundisium, Italy, Sep. 21, 19 B.C.

All his life an invalid, he devoted himself entirely to literary labour. He was the most painstaking of poets, and laboured incessantly at his task. His immortal Æneid he was unable to complete, and left instructions that, as the manuscript could not receive his finishing touches, it should be destroyed. Happily this order was disobeyed by the instructions of the Emperor Augustus.

Volta, Alessandro

b. Como, Italy, Feb. 18, 1745. d. Como, March 5, 1827.

Following up the investigations of Franklin and Galvani, he invented his Voltaic pile, the first instrument which artificially produced electricity, causing that science, with chemistry, to develop with astounding speed and certainty.

Voltaire

b. Paris, Nov. 21, 1694. d. Paris, May 30, 1778.

Born François de Marie Arouet, he assumed the style of Voltaire. His wit gained him admittance to the French Court, but his sharp tongue twice brought him into disgrace. He came to England and consorted with the leading literary spirits of the age, then returned to Paris. Here he got into hot water again, and went ultimately to the Court of Frederick the Great, from whom he parted on unfriendly terms three years later. He settled in Geneva until shortly before his death, when the excitement of a visit to Paris proved too much for him. His literary output was prodigious, his correspondence immense, his influence immeasurable. He had no reverence for good, but he h... an unfailing eye for evil, and denounced unsparingly wherever he found it. He helped free Europe of the oppressive feudal bonds wh... bound it.

Wagner, Richard

b. Leipzig, May 22, 1813. d. Venice, Feb. 13, 1883.

He was a brilliant scholar as a boy, and before he was fourteen had translated a great part of Homer and written a tragedy. Weber and Beethoven inspired him to musical composition, but, in spite of his literary and musical gifts, he had a desperate struggle with fortune. It took him fifteen years to get a hearing for his "Faust" overture, and opera after opera was coldly received. He was often in great distress until Ludwig II. invited him to the Bavarian Court. A special theatre for his works was built at Bayreuth, and gradually his compositions grew in fame. He lived to see the triumph of his genius.

Wallace, Alfred Russel

b. Usk, Mon., Jan. 8, 1822.

Educated as a surveyor and architect, he gave his attention to natural history, explored, and, simultaneously with Darwin, formulated the theory of natural selection.

Walton, Isaac

b. Stafford, Aug. 9, 1593. d. Winchester, Dec. 15, 1683.

At one time a linendraper in London, he settled down to country life, and wrote his famous "Compleat Angler," which, with his classical volume of biographies, ranks as one of our most precious literary treasures.

Washington, George

b. Bridges Creek, Virginia, Feb. 22, 1732. d. Mount Vernon, Dec. 14, 1799.

During the war in America between England and France he fought under the British flag, but in the Rebellion took arms for his native land. He handled his forces with supreme ability, and though it was an army ill-disciplined, ill-fed, and ill-equipped, he led it in the end to complete victory over the English troops. His compatriots would now have made him King, but he was as modest as he was noble, and though he accepted the position as head of the nation, it was only as the elected President of the United States.

Watt, James

b. Greenock, Jan. 19, 1736. d. nr. Birmingham, Aug. 19, 1819.

From the shop of an instrument-maker in London he graduated as mechanic and inventor. To his credit stands the practical steam-engine and steam condenser. With Boulton he established the famous works at Birmingham.

Wellington, Arthur Wellesley, Duke of

b. Dublin, April 29, 1769. d. Walmer Castle, Sep. 14, 1852.

He was the dull boy of the family, yet in his first military action showed genius. He had not much faith in a military career, and unsuccessfully sought civil employment. His chance came in India, where, in the course of eight years, he won great distinction as a leader of men and as an administrator. His supreme honours were not realised, however, until he took command in the Peninsula and drove the French out of Spain and captured Toulouse. For this feat he received £400,000 from Parliament, with honours in abundance from half the nations of Europe. Napoleon's escape from Elba and the subsequent battle of Waterloo took Wellington into the battle-field for the last time, and brought him further distinctions and rewards. Entering political life, he became Prime Minister, but was not in sympathy with popular aspirations, and on one anniversary of Waterloo was besieged by a mob in his own house.

Wells, Henry George

b. Bromley, Kent, Sep. 21, 1866.

The son of a professional cricketer, he was apprenticed to a linendraper, but by perseverance emancipated himself, and became schoolmaster's assistant. A course of study at the Royal College of Science brought him under the influence of Huxley, by whose aid he was able to take first-class honours with his B.Sc. degree. A career as a scientist was prohibited by a breakdown in health. He found his true vocation, however, in letters, in which he was destined to play an important part as a gifted and original writer upon social reform. He is equally impressed by the stupidity of the race and by its immense possibilities.

Wheatstone, Sir Charles

b. Gloucester, Feb. 1802. d. Paris, Oct. 19, 1875.

With W. F. Cooke he invented the instrument out of which has grown the electric telegraph system of the United Kingdom.

Wesley, John

b. Epworth, Lincs, June 17 (o. s.), 1703. d. London, March 2, 1791.

"The Ignatius Loyola of the English Church" distinguished himself as a scholar at Oxford University, and had been curate to his father and a Church missionary in Georgia before entering upon the work in Britain which gave the world a new and mighty religious denomination—the Wesleyan Methodists. No man ever lived a fuller life. Wesley's itineraries of over 250,000 miles, the dangers he experienced, the vast literary labours he accomplished, the wonderful organisation he built up, constitute one of the great romances of modern biography. He distributed vast sums in charity, and, with his brother Charles, wrote a number of hymns still in general use.

White, Gilbert

b. Selborne, Hants, July 18, 1720. d. Selborne, June 26, 1793

"White, of Selborne," was a fellow of Oriel College, Oxford, but became curate of his native Selborne. There he indulged his love of natural history and antiquarian interest, and wrote his immortal work on his observations. The book, a classic beyond price, has done more than any other work in the language to inculcate a love and knowledge of nature.

Whitefield, George

b. Gloucester, Dec. 16, 1714. d. Boston, Sep. 30, 1770.

While at Oxford he was caught by the wave of religious enthusiasm which the Wesleys had started, and accompanied John Wesley on his mission to Georgia. Upon his return he was admitted to Orders, but his burning eloquence and liberal views caused the pulpits of the Church to be closed against him. Thereafter his life was devoted to mission work, in which he had marvellous success. Although there were points of doctrine upon which he and Wesley differed, Whitefield was a very potent factor in the foundation of Methodism. He made seven expeditions on mission work to America, and died there.

Whitney, Eli

b. Westborough, Mass., Dec. 8, 1765. d. New Haven, Conn., Jan. 8, 1825.

In days when the cotton had to be slowly separated from the seed by hand, he gave years of his life to the invention of the cotton-gin. At last he succeeded, but unscrupulous rivals broke into his premises, stole his invention, and made copies of it before he could patent it. The invention, which added hundreds of millions of pounds to the wealth of America, brought him a £10,000 grant from the Government, which su with all his profits, was swallowed up in law su , undertaken to protect his interests. He afterwards realised a fortune as a manufacturer of firearms.

Wilberforce, William

b. Hull, Aug. 24, 1759. d. London, July 29, 1833.

Closely associated with Pitt, though an independent politician, he began as a young man his campaign for the abolition of the slave trade and for the emancipation of its victims. By many of his contemporaries he was deemed a fanatic, but his devotion to the righteous cause he had made his own was crowned with victory after a nineteen years' struggle. The Emancipation Bill, however, was not passed until a month after his death.

Wilkie, Sir David

b. Cults, Fifeshire, Nov. 18, 1785. d. off Gibraltar, June 1, 1841.

He painted before he could write, and though scantily furnished with means, made himself one of the most famous genre painters of his age.

William I., The Conqueror

b. Falaise, Normandy, 1027 or 1028. d. nr. Rouen, Sep. 9, 1087.

His father was Robert III., Duke of Normandy, his mother a tanner's daughter. Although not lawfully entitled to the crown of Normandy, the nobles made him successor to his father. Edward the Confessor, his cousin, promised him the English Crown. Harold pledged himself to help William to gain it; but, at the death of Edward, was himself crowned. William defeated him at Hastings, and was crowned on December 25, 1066. The Conqueror was a born statesman and warrior. He ruthlessly repressed rebellion, he committed many cruel acts of tyranny, but he made England and the English nation, and historians rank him with Alexander the Great, Constantine, and Charlemagne.

William III.

b. The Hague, Nov. 4, 1650. d. London, March 8, 1702.

The son of William II., Stadtholder of the United Netherlands, he was the grandson, through his mother, of Charles I., and married the elder daughter of James II. When the misconduct of the latter caused the English people to turn him from the Throne, William was brought over and crowned King. He carried out many striking reforms, among which was the making absolute of the will of the people, through Parliament, the establishment of our modern system of national finance, control of the Army by Parliament, and liberty of the Press. This he accomplished in the face of many difficulties, and in spite of many attempts upon his life by Stuart adherents.

Wolsey, Thomas, Cardinal

b. Ipswich, 1471. d. Leicester, Nov. 29, 1530.

His father, a grazier and wool merchant, had him educated at Oxford University, and at thirty-five Wolsey had become a royal chaplain. During the next five years he became indispensable to Henry VIII., who found him a powerful ally in peace and war, and made him Lord Chancellor. Thwarted in his designs upon the Papacy, Wolsey aided Henry in the dissolution of the monasteries, but fell from favour when he failed to secure the King's divorce from Catherine of Arragon, and was deprived of his offices. Restored to the Archbishopric of York, he was still obnoxious to lords and commons for his unjust taxation of the nation, and the wanton insolence with which he had behaved. He was now called upon to take his trial for high treason, but died on the way to London. Although a man of many and grave faults, he did much for education, and history has shown that his own ambitions were coincident with the interest of his country as he conceived it.

Wordsworth, William

b. Cockermouth, April 7, 1770. d. Rydal Mount, April 23, 1850.

After completing his education at Cambridge, he travelled on the Continent, and became imbued with Republican sentiments, which afterwards underwent considerable modification. His friendship with Coleridge determined his career as a poet, and a legacy of £900 from a friend made that career possible. His means were further enhanced by an office as distributor of stamps, while with the Poet Laureateship came, of course, the customary pension. Although he travelled now and again to the Continent and to Scotland, his life was passed almost wholly amid the glories of the Lake Country. Wordsworth's influence upon the poetry of the country was second to none.

Wren, Sir Christopher

b. East Knoyle, Wilts, Oct. 20, 1632. d. Hampton Court, Feb. 25, 1723.

The greatest of English architects was a singularly gifted man, and was first notable in helping to perfect the barometer and as a professor of astronomy. The Great Fire of London gave him his opportunity as an architect. He rebuilt St. Paul's Cathedral, and fifty of our noblest churches, and designed a London of noble thoroughfares and magnificent quays Unfortunately there was not available money enough to carry out the scheme, but many buildings in and about London bear witness to his genius.

Wycliffe, John

b. nr. Richmond, Yorks, about 1324. d. Lutterworth, L'trshire, Dec. 31, 1384.

A distinguished scholar of Oxford, where he became Master of Balliol College, he discharged ecclesiastical offices with those of ambassador. Opposed to the corrupt and scandalous system in the Roman Catholic Church of the time, he boldly addressed the people in pamphlets written in English. Previously all writings for public perusal had been in Latin. He also, with assistance, translated the Bible into English, and to his life's end fearlessly carried on his campaign for the worship of God unfettered by enforced confessions to priests, penances, and indulgences.

Xavier, St. Francis

b. Xavier, Navarre, April 7, 1506. d. San-Chian, Canton, Dec. 22, 1552.

"The Apostle of the Indies" was associated with Loyola in establishing the Society of Jesus, and laboured with phenomenal success as a missioner in the Portuguese colonies in the East.

Xenophon

b. Athens, about 430 B.C. d. Corinth, 354 B.C.

A disciple of Socrates, whose memory he defended in a masterly work, he took part in the expedition of Cyrus the Younger against King Artaxerxes Mnemon. After the death of Cyrus, Xenophon succeeded to the command of the 10,000 Greeks, and led them on their celebrated retreat, through 1,500 miles of hostile country, to the sea. As a historian and essayist Xenophon occupies a foremost place.

Ximenes, Cardinal

b. Torrelaguna, Spain, 1436 d. Roa, Spain, Nov. 8, 1517.

Although as Grand Inquisitor he put to death over 2,500 persons in the sacred name of religion, Ximenes was one of the noblest spirits of his age. His virtues made him a Cardinal and Regent of Spain. He governed at eighty years of age with astounding energy and success, broke the feudal spirit of the lawless nobles, restored lands wrested from the Crown, reformed finances, and created educational institutions on a lavish scale. During the time of his might and influence he observed the austerities of the cloister, always wearing under his robes the coarse frock of the Franciscan monk.

Zola, Emile

b. Paris, April 2, 1840. d. Paris, Sep. 22, 1902.

His father, a poor engineer, bequeathed to him nothing but energy and imagination, and Zola's early years were a period of terrible poverty. He succeeded at last in obtaining a situation as clerk, which enabled him to live until he had cut a way with his pen into public attention as a new force in literature. His novels are books of tremendous power, but many of them picture with relentless detail the most detestable features in the worst of lives; they idealise bestiality. He played a heroic part in the rehabilitation of Captain Dreyfus.
